Haynes, Kathleen G., ed. 1998. National Potato Germplasm Evaluation and Enhancement Report, 1997: Sixty-Eighth Annual Report by Cooperators. U.S. Department of Agriculture, Agricultural Research Service, ARS–148, 380 pp.

This progress report includes research results that have not yet been peer reviewed. The findings, when adequately confirmed, will be released through other appropriate channels.

This report is reproduced essentially as supplied by the authors. It received minimal publications editing and design. The author's views are their own and do not necessarily reflect those of the U.S. Department of Agriculture.

Mention of trade names in this publication is solely for the purpose of providing specific information and does not imply recommendation or endorsement by the U.S. Department of Agriculture over others not mentioned.

This publication reports research involving pesticides. It does not contain recommendations for their use nor does it imply that uses discussed here have been registered. All uses of pesticides must be registered by appropriate State or Federal agencies or both before they can be recommended.

While supplies last, single copies of this publication may be obtained at no cost from Kathleen G. Haynes, Vegetable Laboratory, Building 011, Greenhouse 13, BARC–West, Beltsville, MD 20705.

Copies of this publication may be purchased from the National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161; telephone (703) 605–6000.

The United States Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, and marital or family status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at 202–720–2600 (voice and TDD).

To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326–W, Whitten Building, 14th and Independence Avenue, SW, Washington, DC 20250–9410 or call 202–720–5694 (voice and TDD). USDA is an equal opportunity provider and employer.

K.G. Haynes, K.O. DeLong, D. Fleck, M. Bragg, B. Adams, and C. Lagasse

Objectives: The USDA potato breeding program at Beltsville has four main objectives: (1) to develop improved pestresistant germplasm and varieties; (2) to develop improved germplasm and varieties for processing directly out of cold storage; (3) to enhance germplasm for specific characteristics relating to pest resistance, yield, environmental stress, human nutrition and consumer acceptance; and, (4) to develop statistical genetic models for some of the new breeding strategies.

Breeding: Hybridizations in the greenhouse at BARC in early 1997 were made among tetraploid S. tuberosum selections and varieties possessing processing ability or fresh market potential, and late blight, soft rot, or scab resistance; between tetraploid S. tuberosum and tetraploid wild-species hybrids for cold temperature chipping ability; between tetraploid S. tuberosum and diploid S. phureja-S. stenotomum hybrids with high specific gravity; between S. phureja-S. stenotomum hybrids and haploidspecies hybrids for high specific gravity and processing ability; and, among S. phureja-S. stenotomum selections for late blight resistance. In all, 560 tetraploid, 23 tetraploid x diploid, and 197 diploid crosses were successful.

Processing Evaluations: Yield trials for round whites (Tables 1-4), russets (Table 5), and specialty market types (Table 6) were conducted at Echo Lake. These were

planted in a randomized complete block design with four replications of 25 hills on May 28-29, 1997. Plants were spaced 9 inches within the row for all trials except the russet trial, in which plants were spaced 12 inches within the row. After harvest, September 16-19, tubers from each plot were graded, specific gravity was determined by the weight in air and weight in water method, and the ten largest tubers from each plot were cut to determine the presence of hollow heart. Tuber samples were stored at 40°F, 45°F, and 50°F. Tubers were processed out of 40°F, 45°F, and 50°F, and following a three week reconditioning period of 70°F from 40°F storage during January and February for the round white and russet trials. Selections in the specialty market trial were processed out of 50°F on December 5, 1997. For each combination of storage temperature and processing date, five tubers per sample from each plot were processed (20 samples per clone).

Tuber samples from all yield trials except the russets were processed into potato chips by taking 1/16-inch slices from the cross section of each tuber. Slices were rinsed in water and placed on paper towels to remove exceess moisture. Chips were then fried at 340°F in Primex vegetable shortening until bubbling ceased.

Among the most advanced round, white-skinned selections in the program B0178-34, B0564-8, B0564-9, B0766-3, and B1240-1 show promise for the chipping industry, while B1065-61 (a 4x-2x hybrid) looks promising as a fresh market type (Table 1). Among the more recent round, white-skinned selections B1414-6, B1415-5, B1415-7, B1429A-3, B1440-10, B1440-18, B1445-7, B1449-1, B1338-27, B1452-23, and B1477-5 all processed well in January out of the two warmer storage temperatures,

however, with the exception of B1477-5, the yields of these selections were significantly less than that of Atlantic (Tables 2-4). Tubers of B1463-12 were long and particularly attractive. This clone may have some fresh market potential.

Among the specialty market selections in the program, B0811-4 shows promise as a fairly high yielder of small, red skin, yellow flesh potatoes. Heavy skin netting continues to be a major concern in B0811-13. B1491-17 is another red skin, yellow flesh selection with a fairly good yield of attractive tubers (Table 6).

Tuber samples from the russet yield trial were processed into french fries. A 3/8-inch diameter plug was cut from the cross section of each tuber, rinsed, dried, and fried at 365°F for five minutes.

Among the russet selections in the program B9922-11 still shows a lot of promise for either fresh market or processing. Tubers of B1004-8 and B1482-6 were attractive, but yields were very low (Table 5).

This year 75 varieties maintained in our variety collection were evaluated in yield trials with the standard varieties Atlantic and Superior (Tables 7-9) following the procedures used in the specialty market yield trials, with the exception that the last trial was planted on Aroostook Farm instead of Echo Lake. The yield, specific gravity, and chip color out of 50°F storage in December for Grand Falls and Trent were as good as Atlantic. Hollow heart was a severe problem in Red Kote.

The following selections are established in tissue culture and available for distribution to state certification agencies upon written request to K.G. Haynes: B9922-11, B0178-34, B0564-8, and B0564-9.

U.S. DEPARTMENT OF AGRICULTURE AGRICULTURAL RESEARCH SERVICE

Potato Genetics and Enhancement Project - Madison, Wisconsin

R.E. Hannemann, Jr., A.J. Hamernik, M. Ramon, and J.C. Kuhl

Introgression of resistance to late blight and Colorado potato beetle from wild species to cultivated potato.

Efforts to generate hybrids between 2x(2EBN) Solanum tuberosum haploids and 2x(1EBN) Mexican diploid species via embryo rescue and mentor pollen were conducted during the summers of 1995 and 1996. In 1995, 3,077 pollinations were made resulting in 31 seedlings. However, none of the plants were the desired hybrid (Table 1). The failure in obtaining true hybrids was attributed to embryo rescue being performed too late. The approach was repeated during 1996 when 3,288 pollinations were made, resulting in 184 fruits. Embryo rescue was performed between 14 and 20 days after pollination (DAP) and resulted in 3,343 embryos of which 530 developed into seedlings (Table 2). In January of 1997, a unique hybrid was discovered in the population. This diploid hybrid resulted from the cross between the haploid US-W 13089 (Sebago) and S. pinnatisectum (Pl 275233). Its hybridity has been confirmed through morphology, chromosome number and RAPD analysis. resistance to late blight was tested in an unsprayed replicated experiment at UW Agricultural Research Station at Hancock during the 1997 summer where the results indicate a high level of field resistance to the disease (Table 3). At the same time, a second approach using S. berthaultii, a 2x(2EBN) species, was conducted. The hybrids obtained with S. tuberosum haploids were tested for field resistance to late blight and showed a wide range of reaction from highly resistant to susceptible (Table 3).

The Colorado potato beetle (CPB) experiments were initiated during 1995 when 3,625 pollinations were conducted between *S. tuberosum* haploids and 2x(2EBN) species such as *S. buksovii*, *S. chacoense*, *S. raphanifolium*, *S. sparsipilum*, *S. tarijense and S. tuberosum*. During the summer of 1997, 21 families, one backcross, nine PIs, 11 PIs, six controls and one cultivar were tested for CPB resistance in the field using a 7x7 lattice where the "Norland" was used as a spreader. Individual plants were scored weekly for the

number of egg masses, larvae, and adults and percent defoliation. Only those hybrids with *S. chacoense* parents showed high resistance to the insect. However, a wide range of reaction was observed within and between families, especially some individuals with *S. tarijense* parentage tolerate the insect. The defoliation results for 20 of the families and their parents are presented in Table 4. Only defoliation values per families are shown. Although some of them reflect high values for insect attack, some individuals within the family could behave as resistant to the CPB.

Resistance to *Phytophthora unfastens* in Mexican 2x (1EBN) wild Potato Species

The focus of this study is on Mexican diploid 1EBN wild potato species. 1EBN species were selected because to date no known research has specifically addressed the resistance to Phytophthora infestans known to be present in these Mexican derived species. Additionally, the diploid nature of the species will allow for a relatively straight forward evaluation of resistant genotypes as compared to working at a higher ploidy level. Two Solanum species were initially selected for this study, Solanum cardiophyllum subsp. cardiophyllum (cph) and Solanum pinnatisectum (pnt), based on PI evaluations for susceptibility and resistance, respectively. Selection was also based on flowering characteristics and the ability to cross and obtain viable seed. S. cardiophyllum subsp. cardiophyllum P1s were selected from available plants in the field during early Fall 1996, at the UW Lelah Starks Potato Breeding Farm. S. pinnatisectum PIs were selected from previously screened individuals from which tubers were available. Two PIs were selected for S. cardiophyllum subsp. cardiophyllum (5 plants each) and seven PIs were selected for S. pinnatisectum (5 plants per P1).

Detached leaf tests were chosen for the initial determination of resistant/susceptible phenotypes. This decision was based the available resources and the flexibility of being able to screen a large number of individuals in replicated trials over a short period while maintaining the screened plant. Results could later be compared to field trials and/or whole plant evaluations. Initial work with *Phytophthora infestans* included two pathotypes, WI94-1 and ME93-2A, US1-A1 and US8-A2, respectively. The US1 pathotype was included as a control in working out the inoculation protocol previously used. Difficulties arose in implementation of detached leaf protocol such that few or no lesions

were obtained on the susceptible control, Green Mountain. More favorable results were achieved with use of Rye A media for the culturing *P. infestans* and the addition of a cold shock treatment of the inoculum prior to application. Furthermore, four additional pathotypes were obtained from Dr. Ken Deahl, USDA, ARS, Beltsville, including: MSU96 (US8-A2), Colorado-C (US8-A1), 94-31 (US1-A1) and SA96-44 (US1-A1). Screening with detached leaves was delayed during summer field trials.

Reciprocal crosses of the above PIs were generated between S. cardiophyllum and S. pinnatisectum. A total of 2,601 cph x pnt and 801 pnt x cph crosses were completed. One fruit with 4 seeds were recovered from the cph x pnt crosses. A total of 64 fruit and 1882 seeds were recovered from the pnt x cph crosses. It is hoped that by crossing an established resistant individual with a susceptible individual that a segregating population will be generated. Unfortunately until resistant and susceptible individuals can be established, phenotypes are uncertain. Currently one third of the seed from each fruit is being allowed to germinate allowing for the evaluation of seed viability. The recovered plants are being grown in the greenhouse for detached leaf evaluation this fall.

Field tests with naturally occurring inoculum were conducted this past summer at the Hancock field station to determine resistant/susceptible phenotypes to P. infestans of all parental plants, as well as several additional species/PIs that have previously been identified as having susceptibility or resistance to P. infestans. Several complicating factors led to inconclusive results, and the inability to establish the specific responses to *P. infestans*. In particular, the late arrival of P. infestans and the heavy infestation of Alternaria solani (early blight) was such that defoliation data were collected regardless of the causal agent. Results were further complicated with early occurrence of blackleg, leading to significant plant reduction in some treatments, in particular one of the PIs of S. cardiophyllum. The inability to distinguish defoliation specifically caused by P. infestans resulted in observations that reflect total defoliation. Table 5 presents the observed results for those PIs that have been used in crosses to date. From the table it would appear that PI 347759 shows signs of susceptibility, however, this same PI lost many plants to blackleg early in the season. As a result of the inconclusive data, detached leaf tests need to be conducted to determine the resistance/susceptible phenotypes of parental plants.

Once phenotypic characterization of selected individuals can be established molecular mapping techniques can be applied to identify the resistant genotype and compared to previously established resistance on chromosomes 5, 8 and 11. The diploid nature of the selected species will greatly simplify genetic analysis for resistant loci in a segregating population. To date, DNA has been isolated from all plants used in crosses. Forty-seven tomato genomic probes from Tanksley have been selected for use in screening. The selected probes have previously been characterized as having a low number of polymorphic bands and evenly distributed over the twelve chromosomes. Initial screens indicate polymorphisms between and within S. cardiophyllum subsp. cardiophyllum and S. pinnatisectum species/PIs. Once the phenotypes have been established, the parents and eventually the F₁ progeny can be screened for polymorphisms, leading to a molecular characterization of the resistance to *P. infestans* in *S. pinnatisectum*.

Imperative for further progress on this project is the determination of phenotypic response to P. infestans. It must be established that the PIs and specifically the individuals that are being worked with are indeed resistant and susceptible. Once individual phenotypes are characterized a guided approach to crossing will be initiated generating more F_1s , as well as beginning test crosses. Additionally, a more systematic approach may be applied to the collection of RFLP data, focusing on compatible resistant/susceptible parents that have produced viable seed.

Evaluation of Parental Materials and Enhancement Selections for Resistance to Late Blight, *Verticillium* Wilt and Colorado Potato Beetle in Field Tests

To aid us in identification of useful parents and enhancement selections as a part of our joint National Cooperative Enhancement Project effort, we have begun to evaluate our materials in unsprayed plots for resistance to late blight, Colorado potato beetle, and *Verticillium* wilt in an infected field. These tests augment our routine evaluations for yield, chipping, specific gravity, adaptation, etc. which are done at various stages in the development of our materials. The following is a summary of our field data taken on materials entered in these plots this past year at the UW Agricultural Research Station at Hancock.

<u>Late Blight</u>. Six hundred and sixty-five clones were tested for their reaction to natural late blight infection in the field at the University of Wisconsin's

Agricultural Research Station at Hancock. This was a large unreplicated trial, near Dr. Stevenson's (UW Dept of Plant Pathology) late blight trials. Included among these were 118 foreign varieties, 89 foreign breeding stocks, 95 haploid-species hybrids, 25 late blight differentials and 317 enhancement selections (Table 6). Table 7 presents some of the diversity in reaction to late blight observed. In general the check variety, Ranger Russet, was killed by the second reading, August 29. Varying degrees of resistance/susceptibility were expressed over the four readings. By the last reading on September 12, essentially all materials were killed, except for foreign breeding stocks CEX-69-1 (20%), PI 517317 (30%), and the bacterial wilt line MS 35.9 (10%). Heavy early blight infection confounded the readings in this plot. No attempt was made to separate damage from early blight from that of late blight.

In a second field at this location, a number of species (Table 8) were evaluated for field resistance to late blight, as well as hybrid families with potential late blight resistance (Table 9). A sample of the PIs are listed. Excellent resistance is noted for a number of the Mexican species. A sample of some of the clones from the families is also listed. Varying degrees of resistance/susceptibility are indicated, but among these are some excellent resistance responses, with only 20-30 % defoliation at the end of the season.

The information gathered from the late blight differentials (Table 10) indicates only one 1521C (3) showed resistance at the end of the season. Most were heavily infected by the second reading. Again these results are confounded with the response to early blight.

A comparison of late blight readings between 1996 and 1997 was made using the same clones (Table 11). In general, 1997 was a more severe year. Again CEX-69-1 proved to be the most resistant among these lines as did PI 527315. The first readings seem to be correlated between years, but the lack of correlation was evident with the second reading. This may in part be due to confounding with early blight, but could also indicate a different genotype of the fungus was present.

<u>Verticillium</u> wilt. An unreplicated evaluation for <u>Verticillium</u> wilt resistance was planted at the UW Agricultural Research Station at Hancock. Tubers were planted into a field used by Dr. Rouse (UW, Dept of Plant Pathology) for early dying studies and has high levels of the pathogen in it. Six hundred and thirty

clones were tested (Table 6). Only visual symptoms were evaluated. Table 12 lists some of the most resistant materials. These will need to be screened a second year in replicated trials and evaluated more closely to determine their true resistance. Flava, Nevkij and HET 1278-2 showed no visual symptoms of *Verticillium* wilt, early or late blight. Again, early and late blight had a confounding effect on the plot.

Colorado Potato Beetle. Six hundred and thirty-five clones were evaluated for resistance to Colorado potato beetle in unsprayed plots at the UW Agricultural Research Station at Hancock in two unreplicated plots (Table 6). One was near Dr. Wyman's (UW Dept of Entomology) Colorado potato beetle plots. Very little resistance was found in these materials (Tables 13,14). All essentially were defoliated by the beetles by the end of the season, though some held up with 10-30% defoliation until the next to the last reading. High levels of resistance were noted among some families (Tables 15, 16), whose wild species parent had been reported to be resistant to Colorado potato beetle. The species/PIs showing these resistance were S. chacoense or S. tarijense. The best resistance was noted for S. chacoense PI 217451 and for PI 473243.

From this work, we can see that there are some promising late blight, *Verticillium* wilt and Colorado potato beetle resistant materials in the pipeline among enhancement selections and parental materials. These will provide new and augment existing sources of resistance in our cooperative national enhancement effort.

Acknowledgements

We wish to thank University of Wisconsin Agricultural Research Stations for their support at the Hancock Agricultural Research Station and the UW Lelah Starks Potato Breeding Farm at Rhinelander, and the superintendents of those stations, Mr. C. J. Kostichka and Mr. B. D. Bowen, respectively, for their support and for the technical assistance of Mr. A. J. Hamernik, all of whom made this work possible.

NORTH CENTRAL REGIONAL POTATO TRIALS Richard Novy, Assistant Professor and Bryce Farnsworth, Research Specialist, Plant Sciences Dept., North Dakota State University and Cooperators

Cooperators in 1997:

Iowa, Dr. Bill Summers; Louisiana, Dr. Charlie Johnson and Mr.Gil Barker; Michigan, Dr. Dave Douches; Minnesota, Dr. Christian Thill; Nebraska, Dr. Alexander D. Pavlista; Ohio, Dr. Richard Hassell; Wisconsin, Dr. Jiming Jiang, Dr. Horia Groza, and Mr. Bryan Bowen. Technical assistance from Michael Schwalbe in North Dakota is appreciated.

Eight states participated in the North Central Regional Trials in 1997. The Canadian provinces of Alberta and Manitoba will again participate in the trials in 1998.

Cooperating States 1997

Ohio	5/22	9/17	118	D
Wisconsin	4/22	9/15	146	I

¹ I = Irrigated (most irrigation was supplemental to rainfall); D = Dryland

Trial conditions: The overall objective of the trial is to test the performance of advanced selections for uniformity over a wide variety of locations and environments. In most cases, rainfall was supplemented with irrigation. but three sites were dryland (ND, OH, LA). Adverse growing conditions in Iowa and North Dakota (flooding of trial) dramatically lowered yields and did not allow for an effective evaluation of the entries' merits. Their trial results have been included in all tables, but regional averages for Tables 1, 2 and 3, do not include Iowa or North Dakota. Louisiana's trial was flooded early in the growing season with subsequent seed rot. No harvest data was obtained from that site.

Entries: Twelve advanced selections were received from Michigan, Minnesota, North Dakota, and Wisconsin. Seed of the check varieties Norchip, Atlantic, Snowden, Red Norland, Red Pontiac, Russet Burbank, and Russet Norkotah were supplied by North Dakota in order to

ensure a standard seed source. The selections, number of years in the trial (YIT), and descriptions are given below:

Selection	YIT	<u>Description</u>
MN16180	2	pale, yellow fleshed tablestock
MN16489	2	pink-eyed white chipper
MN16966	1	processor with white skin, yellow-flesh
MSB073-2	1	chipper with netted skin
MSB076-2	3	white chipper
MSB106-7	2	russet tablestock
ND2225-1F	2 3	red tablestock
ND2676-10	2	white chipper
ND3828-15	1	white chipper
W1151rus	2	russet tablestock
W1313	2	white chipper
W1348rus	1	russet

Total and US No. 1 Yield: MN16966 (403 cwt/A) MN16489 (396 cwt/A), and MSB0106-7 (394 cwt/A) had the highest total yield across the four irrigated sites. Under dryland conditions at the Ohio site, Red Pontiac (300 cwt/A), MN16966 (291 cwt/A), and MSB106-7 (261 cwt/A) were the top three entries for total yield. MN16489 (354 cwt/A), W1313 (352 cwt/A), and MSB106-7 (349 cwt/A) were the top three entries for U.S. No. 1 yield under irrigation. Under dryland conditions (Ohio), Red Pontiac (246 cwt/A), MSB106-7 (193 cwt/A) and Red Norland (191 cwt/A) were the top three entries for U.S. No. 1 yield. (North Central Regional Trial Tables 1 and 2).

Percent U.S. No. 1: The range for percent U.S. No. 1 was 67% (Russet Burbank) to 93% (Red Norland). Of the selections, MN16489 had the highest percentage of U.S. No. 1 at 87%, followed closely by MSB076-2 and W1313 at 86%. (North Central Regional Trial Table 3).

Maturity: Red Norland was the earliest maturing entry while Russet Burbank was the latest maturing. Among selections, ND2676-10 was the earliest maturing and MN16489 the latest. (North Central Regional Trial

Specific Gravities: W1313 had the highest specific gravity at 1.091, followed closely by MSB076-2 at 1.089. As expected, the lowest specific gravities were observed in the red cultivars and selections (1.060-62). Russet tablestock selections Wll51rus and MSB106-7 had the next lowest gravities at 1.067. (North Central Regional Trial Table 5).

Scab Reaction: Scab ratings were taken and reported from six sites. Minnesota reported the most severe incidence with respect to area and type. The percentage of tubers displaying scab symptoms was highest in the red cultivars and selection with Red Norland at 21.5%, Red Pontiac at 19.8%, and ND2225-1R at 18.2%. A high incidence of scab also was reported for MN16489 (15.8%) and W1313 (16.5%). Scab incidence was lowest in MSB106-7 (0.6%) and W1348rus (0.3%). (North Central Regional Trial Table 6 and Scab column in North Central Regional Trial Table 7).

Summary of Grade Defects: Freedom from external defects ranged from a low of 60.7% (Russet Burbank) to 94.3% (Russet Norkotah), while freedom from internal defects ranged from 66.5% (Atlantic) to 95.0% (MSB073-2) (North Central Regional Trial Table 7).

Chip Color: Chip color results are reported as Agtron values or PCII Color Chart values. Tubers were chipped shortly after harvest. All chipping entries performed as well as Atlantic, Norchip and Snowden. As noted in 1996, MN16180 (classified as a tablestock entry) chipped well and could have potential as a dual-purpose cultivar. (North Central Regional Trial Table 8).

Overall Merit Ratings: The following summary shows the top five entries from 1997 and indicates the total points based on merit rating for these entries over the previous two years. (North Central Regional Trial Table 9).

Selection	1995	1996	1997
W1313	NE	7	13
R. Norkotah	NE	4	12
ND2225-1R	14	6	12
MSB076-2	8	15	10
MN16489	NE	8	9
W1151rus	NE	0	7

^{*}Not Entered

Summary of 3-year performance: MSB076-2 and ND2225-1R had their last trial year in 1997. For merit ratings during the three years, ND2225-1R ranked 5th, 6th (tied), and 2nd (tied), in 1995, 1996, and 1997 respectively. MSB076-2 during the same trials years ranked 6th, 1st, and 3rd. Yield comparisons of the two entries with check cultivars during the three years are shown in North Central Regional Trial Table 10.

Based on four 25 tuber samples (one from each replication). Percentage based on number of tubers. 7/

Number of tubers with scab of 100 tubers rated. Does not count in external defects.

Tubers free from any external defect of any sort. % 4

Percentage of normal tubers showing no internal defects. Individual tubers may have more than one type of internal defect.

¹1995 Yield data for ND2225-1R and check cultivars does not include the ND site.

²Dark Red Norland was used in 1995 and 1996; Red Norland was used in 1997.

³1995 Yield data for MSB076-2 and check cultivars is derived from MI, NE, and OH sites.

NORTHEAST REGIONAL POTATO TRIALS

Jonathan A. Sisson III, Assistant Scientist, University of Maine Agricultural and Forest Experiment Station, Presque Isle, ME.

Cooperators in 1997: Delaware, Ed Kee; Maine, Gregory Porter; New Brunswick, Henry DeJong; North Carolina, Craig Yencho; New Jersey, Mel Henninger; Long Island, New York, Joe Sieczka; Upstate New York, Don Halseth; Ohio, Richard Hassell; Pennsylvania, William Lamont Jr.; Prince Edward Island, Walter Arsensault and Peter Scott; Quebec, Pierre Turcotte; and Virginia, Rikki Sterrett.

Twenty-three trials were conducted in eight states and three Canadian Provinces. Twenty-three named varieties and 21 numbered clones were available to the cooperators. Seed for all clones and varieties were grown by the Maine State Seed Potato Board at Porter Farm. Seedpieces were prepared, cut, and suberized by the staff at the University of Maine Agricultural and Forest Experiment Station in Presque Isle, Maine. Seed was distributed to cooperating locations according to requests received from individual cooperators. Cultural practices were generally similar to those used by commercial growers near each location.

Objectives: The objectives of this regional project are (1) to develop pest-resistant, early maturing, long-dormant varieties that will process from cold storage; (2) to evaluate new and specialty varieties developed in the Northeast; (3) to determine climatic effects on performance to develop predictive models for potato improvement; and (4) determine heritability/linkage relationships and improve the genetic base of tetraploid cultivated varieties.

Results: Total yield, marketable yield, specific gravity, tuber size, tuber defects, chip color results, boil and bake results are presented in Northeast Region Trial Tables 1-7. For round whites, AF1480-5, AF1615-1, B0766-3, NY102, NY103, Atlantic, Itasca, Katahdin, Kennebec, and Reba produced good yields in many locations. Of these ten selections, Atlantic, NY102, and B0766-3 had the highest specific gravities. Atlantic, Katahdin, Kennebec, Reba, AF1480-5, B0766-3, NY103, and Yukon Gold produced good sized tubers (2.5 to 4 inch diameter). Atlantic, AF1480-5, B0766-3 and Itasca had hollow heart problems in some locations. AF1615-1, NY103, Katahdin, and Kennebec were prone to sunburning in some trials. Reba and NY102 had few

external and internal problems.

For red clones, Chieftan produced the highest marketable yields in most trials and had the largest tubers. Cherry Red had the highest specific gravity but also had some hollow heart. Chieftain had both good boil and bake scores, while the others did not bake as well.

Century Russet yielded and sized similar to Russet Burbank in most trials. Russeting was very light or nonexistent on Century Russet tubers and it had some hollow heart problems. B1004-8 did poorly at most sites. B9922-11 produced the largest tubers in most trials and had a similar specific gravity to Russet Burbank.

MaineChip has produced the lightest chips over the years; however, the yields have been very low. ND2471-8 has chipped very well out of the field, but has done very poorly out of storage. B0564-8, NY102, NY103, Snowden, AF1427-7, AF1433-4, and NorValley have chipped well out of the field, and have usually chipped well out of warm storage. Reba has consistantly chipped well both out of the field and out of warm storage. Monona has chipped very well after reconditioning. Reba, AF1424-7, AF1433-4, and W870 have also produced light chips after reconditioning.

If you would like a copy of the 1997 Northeast Potato Trials, contact Jonathan Sisson at sisson@maine.maine.edu.

WESTERN REGIONAL POTATO VARIETY TRIAL

J. J. Pavek, D. L. Corsini, and Cooperators

Uniform Potato Yield Trial

The 1997 trial was grown at twelve locations for yield; disease data are from three of the locations. Eighteen entries, 14 experimental, three standard checks, and one early check, were grown. Three locations grew entries for both early and late harvest. The trial locations, dates of planting, vine killing, and harvest, and

Pavek, Breeder, and Corsini, Pathologist, USDA-ARS, Univ. of Idaho, PO Box AA, Aberdeen, ID 83210. Cooperators: California, R. Voss; Colorado, D. Holm; Idaho, S. Love; New Mexico, C. Owen, R. Baker; Oregon, A. Mosley, D. Hane, K. Rykbost, C. Shock, S. James; Texas, D. Scheuring, J. C. Miller, Jr.; Washington, R. Thornton, N. Fuller, C. Brown.

days from planting to vine-kill/harvest are shown below. Cultural practices and the use of fertilizer, herbicides, pesticides, and vine killing varied according to local needs. Trial plots at all locations were irrigated on a regular schedule throughout the entire growing season according to plant needs. The growing season was cooler and wetter than normal across the region.

Data on vines, tubers, yield, internal quality, disease reactions, merit scores, and disposition are presented in Western Tables 1 through 7. Three clones finished three years of testing, and will be tested further locally. Two clones were dropped, and the rest will continue in testing. The five Russet Norkotah strains showed much promise for fresh use; AO87277-6 was at the top for processing quality.

1.0 (poorest) to 5.0 (best).

² Composite scores for Ab & Kim, and for Krn & Tul early and late trials.

RTC = regional testing completed (3 yrs), CONT = continue in trial, DROP = drop from trial, CHECK = control.

CALIFORNIA

R. Voss, H. Phillips, J. Nunez, D. Kirby, F. Laemmlen, R. Mullen, R. Smith, J. Valencia, M. Jimenez

OBJECTIVES

The major objectives of the California Potato Variety Selection and Development program are 1) obtain or develop new russet, white, red, processing and specialty varieties of improved adaptability and quality, 2) demonstrate the characteristics of the many new varieties and advanced selections being developed in the U.S., Canada and Europe, 3) determine relative resistance/susceptibility of named varieties and advanced selections to common diseases, insects and environmental stresses, and 4) assess cultural requirements of advanced selections and new varieties.

SUMMARY:

Large, comprehensive evaluation trials were grown in Kern County and Tulelake Intermountain Research and Extension Center (IREC). In addition, small trials were conducted in grower cooperator fields in numerous other locations - Santa Maria, Humboldt Co., Placer Co., Salinas Valley, Kearney Ag Center, and Stanislaus Co. The trials conducted included 1) Western Regional early russet, late russet, chipping, specialty and red trials - Kern, Tulelake; 2) Snack Food Association nationwide uniform chipping trial - Kern; 3) Replicated early and late trials, with different harvest dates -Tulelake: 4) Replicated trials of commercially grown varieties - Tulelake; 5) Late Blight resistance screening at UC Cotton Research Station near Shafter - Kern: 6) Russet Norkotah seed source trials - Kern County and Tulelake; 7) Potato Virus Y

effect on Russet Norkotah growth and yield - Tulelake; 8) Six county/grower replicated trial of russets (1) chippers (1), reds and specialty (4), 9) Observation trials of 5-hill, 12-hill, 27-hill and 2X27-hill entries - Kern and Tulelake; 10) Storage evaluation trial at Tulelake, and 11) Seed increase block in Stockton Delta.

The highest rated russets were, A8792-1, AC87079-3, AC87084-3, AC87138-4, AO87277-6, CO85026-4, Legend, Russet Norkotah TXNS278, Russet Norkotah #3, Russet Norkotah #8 (both from Colorado), Russet Norkotah TXNS112, (both from Texas)

The highest rated reds were Ciklamen, DT6063-1R ('Cherry Red'), IdaRose (AD82745-1, A82705-1), Modoc, NDO2438-6, NDO2438-7, NDO2686-4, NDO2686-6, NDO4588-5, NDO4592-3, NDO4300-1, NDO5108-1.

The highest rated chippers were A8961-14, AC87340-2 ATX85404-8, Chipeta, CO87106-5, FL-1900, FL-1896, FL-1625, FL-1533, FL-1879, NY103 and Snowden.

The highest rated long whites were AD84087-1, ND2050-1 and Tejon.

The highest rated specialty types in were Agria, Albina, Dali, G742-4X, German Butterball, Granola, Latona, Vera, and Vital.

A Late Blight resistance screening trial was conducted in Kern County. Despite inoculation, no late blight disease infection occurred in any of the plots. Thus, no new information on potential resistance/tolerance was gathered at Shafter. However, in 1996, excellent results were recorded. The most "resistant" or "tolerant" of the 100 entries,

which included the USDA uniform trial. were AO84275-3, NDD840-1, B0767-2, AWN85542-1, Calrose, H5954, AO80432-1, B0718-3, H-5978, and Bzura. Pathogen type was primarily g11 (US11?). Late blight was observed, for the first recorded time. in the Tulelake area in 1997. It occurred in numerous commercial fields as well as in our variety experimental plots at IREC. Relative disease ratings were obtained on the observational plots only. Among those with no disease were five of the seven lines from the late blight breeding program at USDA -Madison, Wisconsin - J101K6A22, K101K9, J103K7, J101K27, K138A12. The others were AWN86514-2, AC91848-2, AC91814-1, A8961-14, B0718-3.

Russet Norkotah seed source trials in Kern Co and at Tulelake indicated a wide range of vield potentials, just as they did in 1996. In Kern County, 33 seed lots ranged from 305 cwt/A to 575 cwt/A of No. 1's. At Tulelake, 55 seed lots, including the same 33 as planted in Kern County, ranged from 245 cwt/A to 455 cwt/A of No. 1's. Also like 1996, of the 30 lots planted in both locations, the relative ranking of yields was not consistent. For example, several of the highest yielding lots at Kern County were among the lowest at Tulelake, and vice versa. The clonal selections from Colorado and Texas, Colorado RN #3, Colorado RN#8, Texas TXNS112 TXNS223, and Texas TXNS278, had greater vine growth, generally, higher yields than the 'standard' clone:.

Russet Norkotah Potato Virus Y Trial.

One of the possible reasons for the variable performance of Russet Norkotah is Potato Virus Y (PVY) infection. Visual symptoms are not always readily apparent in this variety, thus infection and spread can occur

before it becomes obvious. Two seed sources were identified, with 0% and 60% of the tubers infected with PVY. The two lots were mixed in different proportions to produce five levels of PVY tuber infection. Identical trials were planted at IREC (Tulelake), the Klamath Experiment Station, and at Hermiston, Oregon in the Columbia Basin. In 1996, at Tulelake, the rate of decline was approximately 1 2/3 cwt/A in total yield for each 1% increase in PVY seed infection. The rate of decline was approximately 1 1/3 cwt/A in No. 1 yield for each 1% increase in PVY infection. The experiment was duplicated in 1997.

Leaf samples were collected early, mid and late season and laboratory assayed to determine the extent of PVY spread from non-infected to infected plants. At Tulelake, in 1996, very little PVY spread had occurred by the end of June. Yields corresponded to the amount of PVY present in the seed at planting time. Total and No. 1 yields both decreased linearly as PVY infection increased. Since disease spread did not occur during the season, the yield reduction was less than in 1996 - only approximately 75 lbs/A (3/4 cwt/A) for each 1% increase in PVY in the seed. This decrease rate was equally applicable for Total and No. 1 yields. Almost all of the yield differences were reflected in large tubers, >12 oz. At Hermiston, with heavy aphid pressure, near total PVY infection occurred early in the season; the resultant effect on yield was much more dramatic than at Tulelake. At Klamath Falls, infection increase was similar to Tulelake.

New Releases

CalWhite release was formalized jointly with USDA and Univ. of Idaho.

COLORADO

D. G. Holm and J. D. Wick 1

Objectives

The major objectives of the Colorado breeding program are: (1) to develop new potato cultivars (russets, chippers, and reds) with increased yield, improved processing and fresh market quality, resistance to diseases and pests, and tolerance to environmental stresses; and (2) to provide a basic seed source of selections for possible seed export.

Breeding Program

Fifty-one parental clones were intercrossed in 1997. Seeds from 193 combinations were obtained. Seedlings from selected families will be produced in 1998 for initial field selection in 1999.

Another thirty-six parental clones were intercrossed in early 1998. Primary emphasis of this crossing block was specialty types (yellow fleshed reds, whites, and russets, and colored fleshed chippers).

One hundred seventeen 1996 seedling families were grown in the greenhouse producing 41,300 seedling tubers for initial field selection in 1998. Surplus tubers (second thru forth sizes) will be distributed to Idaho, Minnesota, Oregon, Texas, and Alberta, Canada.

A second, smaller planting of seedlings representing 14 families was grown in the greenhouse. These families resulted from 1994 crosses emphasizing specialty types and will also be planted for initial field selection in 1998.

Additional seedling tubers were obtained from Dr. J. J. Pavek, USDA-ARS, Aberdeen, Idaho; ; Dr. Dermot Lynch, Agriculture Canada, Lethbridge, Alberta; and Dr. J. Creighton Miller, Texas A&M University, College Station, Texas.

Selection Program

A total of 73,324 first-year seedlings were planted with 820 being selected at harvest for further observation. Another 936 clones were in 12-hill, preliminary, and intermediate stages of selection. Of these, 262 were saved at harvest for further evaluation. Twenty-five advanced selections were saved and contingent on additional evaluations, will be increased in 1998. Another 153 selections were maintained for germplasm development, breeding, other experimental purposes, or seed increases for the Texas program.

Advanced Yield Trial. Twenty-two clones, 18 advanced selections and 4 cultivars, were evaluated in the Advanced Yield Trial. Results on yield, grade, and processing characteristics are summarized in Tables 1 and 2.

Several selections had yields greater than 400 cwt/A. Clones yielding greater than 500 cwt/A were AC87138-4, AC89536-5, and CO90052-1. Avalanche was the highest yielding cultivar with 707 cwt/A.

Selections producing acceptable fry colors were AC83064-6, AC87138-4, and COO83008-1.

Two russet selections, AC88042-1 and AC88165-3, will be entered in the 1998 Western Regional Main Trials. Seed of these selections will also be released for grower trials in 1998.

Western Regional Main Trial. Eleven selections and five cultivars were entered in the Colorado Western Regional Main Trial.

The number of entries in this trial has been significantly reduced since 1995. This is due to the exclusion of all entries coming from areas where seed stocks potentially have been exposed too late blight. We are attempting to initiate tissue culture based increases of all potential entries from the various cooperating programs two years in advanced of entrance in the Western Regional Trials (Main, Chip, Red, and Specialty).

¹Holm and Wick are Professor and Research Associate, respectively, San Luis Valley Research Center - Colorado Agricultural Experiment Station, Department of Horticulture and Landscape Architecture, Colorado State University, 0249 East Road 9 North, Center, CO 81125.

Selections entered by Colorado in 1997 included AC87084-3, CO85026-4, CO87009-4 and Russet Norkotah S3 and S8. CO85026-4 graduated from the Western Regional Trial having completed three years of evaluation in 1997. Selection CO87009-4 was withdrawn and discarded from further evaluations because of poor performance overall.

The top yielding selection was A82360-7 (552 cwt/A). The 1997 production year was ideal for Russet Norkotah in San Luis Valley trials. All of the line selections still had greater total and US #1 yields compared with the standard. Russet Norkotah S3 performed better than any of the other clonal selections.

The Russet Norkotah clonal selections responded similarly in the postharvest evaluations. One notable exception was that Russet Norkotah S3 had a longer dormancy than any other selection in the trial. This observation should be validated in future studies.

Selections with acceptable fry scores were A82360-7, AC87084-3, CO87009-4, and TX1385-12RU.

Colorado will reenter AC87084-3 and Russet Norkotah S3 and S8. New entries from Colorado in 1998 will be AC88042-1 and AC88165-3.

Results of this trial are presented in the Western Regional Trial report elsewhere in the publication.

Western Regional and Advanced Chipping Trial. The Colorado Western Regional Chip Trial also included intermediate and advanced chipping selections from the selection program that were not formally entered into the regional trials. Eighteen entries, 13 selections and 5 cultivars, were included in the Colorado Western Regional Chip Trial. Trial results are presented in Tables 3 and 4.

Colorado entered AC88357-3 in the 1997 Western Regional Chip Trials. This selection was discarded from further evaluation because of poor performance overall.

The highest yielding selections were AC89653-3 and ATX85404-8. Chipeta had the overall highest total and US #1 yield of 514 and 429 cwt/A, respectively.

Several selections showed susceptibility to black spot bruising. Some of these selections have not shown

susceptibility in the past. Overall, blackspot was more severe in our 1997 trials.

Two selections, CO90217-1 and CO90217-4, have "cold" chipping potential. These selections resulted from a cross of ND2008-2 and ND1995-1.

Selection AC87340-2 will be entered in the 1998 Western Regional Chip Trials.

Colorado initially entered BC0894-2 into the Western Regional Chip Trials in 1994. This selection graduated from the trial in 1996. This selection is early maturing and continues to show potential for eventual naming. BC0894-2 was also entered into the Snack Food Association (SEA) Trials in 1995-1997. Another selection with considerable potential is Texas selection ATX85404-8. It will be entered in the SFA Trials for the third year in 1998.

Western Regional Red Trial. The Colorado Western Regional Red Trial also includes intermediate and advanced red selections from the selection program that were not formally entered into the regional trials. The Colorado trial included 13 entries, 10 selections and 3 cultivars. Trial results are summarized in Table 5.

Entries from Colorado in the Western Regional Red Trial included CO86142-3 (NDTX302-1 x Redsen), CO86218-2 (Sangre x NDTX9-1068-11R) and DT6063-1R. CO86142-3 and CO86218-2 were in the trial for a fourth year because of a lack of entries in 1997. These two selections will not be reentered in 1998. DT6063-1R completed two years of regional testing in 1997 and will be reentered in 1998. Selection CO86142-3 has been discarded due to tuber dry rot and susceptibility to PVY.

Several red selections are early maturing and have relatively high yields. Several red selections also showed susceptibility to blackspot bruising. As observed in the chip trial, blackspot bruising was more severe in 1997.

Selection CO89097-2 will be entered in the Western Regional Red Trials in 1998.

Grower Evaluations. Grower evaluations were conducted on eight russets (AC78069-17, AC83064-1, AC83064-6, AC87084-3, CO80011-5, CO81082-1, CO86026-4, and CO87009-4), two chipping

selections (ATX85404-8 and BC0894-2), and two reds (CO86218-2 and DT6063-1R).

Selections AC78069-17 and CO81082-1 were discarded after several years of grower evaluation. CO87009-4 was also discarded because several lots had mediocre yields due to a lack of tuber sizing. Comparative data for the remaining selections and standard cultivars is presented in Table 6.

Selections to be named in 1998 included CO80011-5 (Crestone Russet) and AC83064-6. DT6063-1R will be named after another year of evaluation in the Western Regional Red Trial. Selections that will continue undergoing grower evaluation are AC83064-1, CO85026-4, AC87084-3, ATX85404-8, BC0894-2, and CO86218-2.

Two new russet selections to be evaluated by growers in 1998 are AC88042-1 and AC88165-3. AC88042-1 is a medium maturing dual purpose clone with processing and fresh market potential. It was selected from a cross of Norking Russet x A81286-1. AC88165-3 is also a medium maturing fresh market clone selected from a cross of A81323-38 x Ranger Russet.

Idaho

S. Love, J. Pavek, D. Corsini, P. Bain, M. Ruby, J. Stimpson, D. Inglis, and M. Powelson

A major objective of the Idaho potato variety development project is to evaluate germplasm produced by the USDA/ARS potato breeding program located in Aberdeen, Idaho. These evaluations include variety trials, herbicide screening, culinary tests, and disease screening. The major emphasis is placed on developing long shaped, russet skinned varieties which have superior fresh market and french fry processing (dual purpose) quality. Some effort is also spent developing chipping varieties.

Replicated Variety Trials

Ten potato variety trials were conducted in 1997 at Rexburg, Shelley, Aberdeen, Kimberly and Parma, Idaho (Tables 1-10). Rexburg is located in the high elevation area of eastern Idaho and has the coolest, shortest season (120 days) of the four sites. Shelley and Aberdeen are located along the Snake River in eastern Idaho, are slightly warmer, and have a 130 day season. Kimberly is located in south-central Idaho and has a 140 day growing season. Parma is located in the warmer area of western Idaho and has a 160 day season. Trials at Aberdeen, Kimberly, and Parma were located on University of Idaho experiment stations, while the trials in Rexburg and Shelley were placed in growers fields. All trial sites were located within major potato producing areas.

The trials were planted between April 2 and May 16 and harvested between September 12 and October 6. Crop management practices were typical of those used in the region in which the trial was located. All trials were planted using a randomized complete block design with either four or six replications. Plots consisted of single rows, twenty feet long.

Following harvest the potatoes were weighed, graded, and sampled for internal quality evaluations. Depending on the specific objectives of the trial, samples were taken for evaluation of blackspot and shatter bruise susceptibility, presence of internal defects, specific gravity, french fry color, and dry matter yield.

Six of the ten trials were conducted to evaluate dual purpose russet or long-white, processing

selections (Tables 1-6). Two were conducted to evaluate chipping selections (Tables 7,8). Two were designed to evaluate selections for high dry matter yield with intent to identify clones superior for dehydration purposes (Tables 9,10).

The trials in Rexburg and Shelley included the most advanced russet breeding selections from the Aberdeen program (Tables 1,2). The unreleased entries had total yields equal to or higher than, and U.S. No 1 yields considerably higher than, Russet Burbank. The lowest yielding clones in these trials were Russet Norkotah and its line selection TXNS278. All of the unreleased selections in these trials had acceptable specific gravity, all but A86102-6 had acceptable french fry color, and all but COA90101-2 had low levels of internal defects.

The trial at Parma was designed to provide information on processing quality of advanced selections under the stressful growing conditions of western Idaho (Table3). All but A8495-1 and COA90101-2 had high yields at Parma. Russet Burbank, A8893-1 and COA90101-2 had high levels of hollow heart. All unreleased clones had lower levels of sugar-ends than the checks, and all but COA90101-2 had acceptable fry color.

Advanced russet selections, including clones in their fifth to fifteenth year of evaluation, were grown at Aberdeen and Kimberly (Tables 4,5). Of the thirteen selections in the trial, five had higher total yields at both locations than did Russet Burbank. All entries (except AO82611-7 at Aberdeen) had a higher percentage of U.S. No 1's, and all but two (A89384-10 and A9148-3) had a higher yield of U.S. No. 1's at both locations. Clones with a good combination of yield, specific gravity, fry color, and merit (appearance) scores included A81386-1, A8495-1, A88338-1, A9014-2, and AO82611-7.

The Tri-state trial represents the stage of evaluation beyond the advanced yield trials and includes locations in Oregon and Washington. In the Idaho location of this trial, A88338-1 and AO89128-4 were acceptable for all yield and quality parameters (Table 6). The other selections were low in yield or poor in appearance.

In the Idaho location of the Western Regional chipping trial, only the clone A88431-1 performed well enough to be considered for further evaluation. It had acceptable yield, exceptionally high specific gravity, outstanding chip color from both warm and cold storage. A8961-14 had good yield and adequate specific gravity, but show some chip color problems and frequent heat necrosis.

In the advanced selection chipping trial A88431-1 was the lowest yielding clone. (Table 8). Clones with a good combination of yield, specific gravity and chip color included A90450-16, A90467-14, A91746-8, and A91790-13.

Every clone tested in the advanced high dry matter trial produced a substantially higher yield of dry matter than did Russet Burbank (Tables 9,10). The superior dry matter yields were the result of a combination of high tuber yield and high tuber solids. The highest yield of dry matter at both Aberdeen and Kimberly was achieved by A82360-7. This is consistent with the results obtained for the past several years. Other outstanding clones were A8792-1 and A89219-7.

Sensory Evaluations

Five advanced breeding selections were compared to Russet Burbank in blind sensory evaluations of baked tubers. These evaluations were conducted by University of Idaho Extension personnel at the Bingham County Extension Office. Tubers were baked in a convection oven, then rated by trained panelists for color, texture, flavor, and overall quality. The evaluations were done twice, once within a month of harvest and again after five months of storage at 40°F.

In the fall evaluation, all five selections were similar to Russet Burbank for flavor and for overall sensory quality (Table 9). Some differences were present for the individual sensory categories. Russet Burbank had the lowest color rating, while AO82611-7 had the highest. A8495-1 and Russet Burbank had the highest texture rating of any clones in the trial. A82360-7, A8792-1, and AO82611-7 were inferior to Russet Burbank for texture.

After five months of storage, A8495-1 was the highest rated clone in every sensory category except color. This was similar to tests from 1996 when it was ranked highest in all categories following a period of storage. A8495-1 was rated best for

overall quality while the remaining selections were similar to Russet Burbank. In general the unreleased selections were better than Russet Burbank for color and similar with respect to the other categories.

Metribuzin Screening

Eight varieties and thirty breeding selections were tested for response to the herbicide metribuzin (Secor/Lexone). Estimations were made for percent foliar injury and measurements taken for vigor following a postemergence (8-10 inch plants) application of 1.0 lb a.i./A. Yield loss for each clone as a result of the application was predicted using a previously developed model which incorporates injury and vigor as inputs. Each variety or selection was assigned a relative resistance score based on yield loss in comparison with varieties of known response.

Exceptionally severe injury resulted from the metribuzin application in 1997 (Table 12). The known varieties responded in the expected fashion relative to one another, but yield loss was high. Shepody was very susceptible, and most plants died resulting in a predicted yield loss of 100%. Atlantic also showed a susceptible response. Russet Burbank was moderately resistant, and Russet Norkotah very resistant to injury. Most of the russet and longwhite selections were resistant or very resistant to injury. The two obvious exceptions were selections AC87084-3 and CO87009-4 from Colorado which both showed high levels of injury.

The chipping and red selections showed a mixed response. Of special note were ATX85404-8 and AC88357-3, which were very susceptible and susceptible, respectively. NorValley and A88431-1 were moderately susceptible to injury.

Of the red clones, NDO2686-6R was susceptible to injury, while COO86107-1R, CO86142-3, and NDO2438-6R were moderately susceptible.

Disease Screening

Potato varieties and selections were evaluated for response to several important diseases, including Verticillium wilt, early blight, common scab, soft rot, and late blight.

Verticillium wilt, early blight, common scab, and soft rot: Breeding selections and standard cultivars were evaluated for their reaction to diseases that commonly occur in Idaho. Verticillium wilt, early blight, and common scab evaluations were done in fields at the University of Idaho Research Center, Aberdeen. Trials were grown in two fields as randomized complete blocks with three replications. Natural soilborne inoculum of V. dahliae occurred at both sites, and early blight spreader rows of cv Pioneer were interplanted with plots at one site. It is expected that early blight symptoms would have been more severe if contact fungicides for late blight control had not been used. No late blight occurred in the plots. The growing season was unusually cool and wet through July. Soft rot evaluations were done by inoculating tuber samples harvested from one of the test sites in mid September using 10⁶ cells/ml Erwinia carotovora var. atroseptica. Tubers were evaluated after 5 days incubation in a mist chamber at 20°C. The least significant difference test was used to separate means.

Advanced selection A83008-8 showed the best Verticillium and early blight resistance of all clones tested, and also had good soft rot resistance. The new variety Umatilla Russet showed Verticillium wilt susceptibility similar to Russet Burbank but was slightly more susceptible to early blight. Four Russet Norkotah clonal selections, CORN*, TXNS112, TXNS223, and TXNS278 tended to have less susceptibility to early dying disease than the standard variety (not significant however at $p\!=\!0.05$).

Late blight: Arrangements were made to screen breeding material for late blight resistance in Corvallis, Oregon, and Mt. Vernon, Washington. The trials were conducted by Mary Powelson and Debra Inglis, respectively.

In both locations artificial inoculations were used to augment natural infection. Disease response was measured by monitoring disease progress and calculating Area Under the Disease Progress Curve (AUDPC). At Corvallis, the amount of tuber rot was also documented. Determinations of late blight strains were made at season's end. At Mt. Vernon two strains made up the majority of samples determined, including US11(A1) and US8(A2), while at Corvallis US8(A2) was present.

A wide range of responses to late blight were found among the clones in the trials (Tables 14,15).

All of the included named varieties commonly grown in North America were very susceptible to foliar blight at both locations. At Mt. Vernon, four named varieties had good resistance, Bzura, Brador, Alpha and Elba. (Table 14). Other clones with good resistance were A84118-3, A90586-11, AWN86524-5, and A82360-7. At Corvallis the trial included mostly clones which were a part of the western regional trials. Only the clone A88338-1 showed an appreciable amount of resistance to foliar blight. Although most clones were susceptible to foliar blight, many showed good resistance to tuber blight. These included A8792-1, A88338-1, AO82611-7, COO83008-1, and Atlantic.

Summary of Promising Breeding Selections

A81473-2: This selection will be released in 1998. It is an oblong russet with a very late vine and has performed best in the long season areas of western Idaho, Oregon, and Washington. It is the result of a cross between A75175-1 (Targhee x A67490-3) and A75188-3. A81473-2 was only grown at Parma in 1997 (Table 3) where it perfomed acceptably. It also had a higher yield and percentage of U.S. No. 1's than Russet Burbank and had higher specific gravity, less hollow heart, and fewer sugar-ends. In 1997 there were 366 acres of certified seed produced of A81473-2.

A82360-7: This oval, lightly russetted clone was developed specifically for dehydration purposes and selected for maximum dry matter yield. It is the result of a cross between A77182-1 (Atlantic x Lemhi Russet) and A75188-3. A82360-7 has shown potential for french fry production as well as dehydration. It was the highest yielding clone in every trial in which it was included in 1997, except at Rexburg, where it was second highest (Tables 1,2,9,10). In the high dry matter trial at Aberdeen, it produced 176% of the dry matter of Russet Burbank, while at Kimberly it produced 185%. This clone is currently being evaluated in commercial production trials. In 1997, there were 3 acres of certified seed produced.

A82705-1R: This red clone is a dark red, high yielding selection that has good storage characteristics. It is one of the few selections tested that competes for yield with Red LaSoda in Idaho. It is the result of a cross between Sangre and TXA218-7 (NDTX9580-6R x Viking). A82705-1R will be released in 1998 under the name IdaRose.

A8495-1: This long, russetted clone yielded similarly to Russet Burbank in all Idaho locations except Parma. It has excellent appearance combined with outstanding processing quality. It is the result of a cross between A77182-1 (Atlantic x Lemhi Russet) and Russet Norkotah. In 1997, A8495-1 had higher yields than Russet Burbank at all locations except Kimberly and Parma (Tables 1-5). In every trial, it had a higher percentage of U.S. No. 1's, fewer internal problems, and higher specific gravity. It had the best overall fry color of any russet clone tested. This selection will likely be released in late 1998. In 1997 there were 42 acres of certified seed produced.

AO82611-7: This long, russetted clone is an Oregon selection of an Aberdeen seedling. It was the result of a cross between Butte and A77268-4 (Lemhi Russet x Norchip). Oregon is currently pursuing release of this clone under the name Umatilla Russet. In 1997, it generally had high yield, good grade, high specific gravity, and showed some resistance to sugar ends (Tables 1-5). This is consistent with previous years. AO82611-7 appears to be adapted to areas with long, warm growing seasons and performed very well at Parma.

COO83008-1: This long, russetted clone is an Oregon selection of a Colorado seedling. It resulted from a cross of Century Russet and WNC672-2 (A6334-20 x Lenape). Release is currently being pursued by Oregon using the name Russet Legend. COO83008-1 had higher yield than Russet Burbank at Rexburg and Shelley (Tables 1,2). It also had a very high percentage of U.S. NO. 1's and excellent internal quality. In 1997, a persistent problem with stem end discoloration was again observed in tubers stored for more than three months. Some tendency for this problem had been seen in past years.

NDO1496-1: This round, white chipping clone is an Oregon selection of a North Dakota seedling. It is the result of a cross between ND292-1 and A77268-1 (Lemhi Russet x Norchip). Due to susceptibility to shatter bruise, Oregon researchers dropped NDO1496-1, and it is now being evaluated by the Idaho industry. In 1997, it was grown in one trial at Aberdeen where it had lower yield and smaller size than Atlantic or Chipeta (Table 8). It had specific gravity similar to Atlantic and chip color better than any of the standard varieties. NDO1496-1 has shown the ability to chip acceptably from cold storage and to recondition well. It has

performed well in processor trials and will likely be released in 1998.

¹ Evaluations were made by trained panelists using double blind procedures. Approximately 100 tests were done on each clone. Each baked potato was rated for color, texture, flavor, and overall appeal. Ratings were made using a 1-9 scale with 9 = best. Means were separated using Duncan's Multiple Range Test, and means followed by the same letter are not significantly different.

¹ Metribuzin applied postemergence (8-12 inch plants) at a rate of 1.0 lb a.i./A (17.5 gpa, 30 psi).

² Plant injury was recorded as the percentage of foliage from an average plant in each plot that showed typical metribuzin symptoms (chlorosis, necrosis, vein clearing, etc.)

³ Predicted yield reduction is expressed as percent loss compared to untreated plots and was calculated using the following equation: Yield reduction = [1-(1.142 + 0.176 (Log (plant height treated/plant height untreated))-0.00796 (plant injury)] x 100.

⁴ VR = very resistant, R = resistant, MR = moderately resistant, MS = moderately susceptible, S = susceptible, VS = very susceptible.

Maine

G.A. Porter, J.A. Sisson, B. Bradbury, B. MacFarline, and P. Wardwell University of Maine; Orono, ME 04469

Introduction: Potato variety trials were conducted at three locations in Maine as part of the NE184 Regional Project (Development of New Potato Clones for Environmental and Economic Sustainability in the Northeast). Thirty-eight potato varieties and clones were tested at Aroostook Research Farm, Presque Isle, Maine. Eighteen NE184 varieties and lines were tested on a commercial farm in East Corinth (central Maine), while thirty varieties and lines were tested on a commercial farm in St. Agatha (northern Maine). The primary objective of all of the Maine trials is to determine performance, quality, and storage characteristics of promising potato clones and new varieties in Maine.

Methods: Single-row plots, 25 feet long, were utilized for the NE184 trials. All trials were hand planted using randomized complete block designs and four replications. The seedpiece spacing used for each line is listed in subsequent tables. Details of important management practices are presented in Maine Table 1. At the Presque Isle site the varieties were grouped so that separate tests could be vinekilled and harvested based on maturity classification. Remaining cultural practices were similar to those used on commercial farms in the area. Specific gravity was determined at harvest using the weight-inair/weight-in-water method. Hollow heart ratings indicate the number of hollow tubers observed per 40 large tubers examined. Unless noted otherwise chip color evaluations were conducted during December following storage at 50°F. Chips were fried at 350°F for three minutes and evaluated using an Agtron M35, calibrated with the black "0" disk = 0 and the white "90" disk = 90. Chips were crushed and reported values are means from four replicates per variety. Each sample was read three times with thorough mixing between readings.

Results:

Rainfall, General Growth, and Plant Stands.
Rainfall by month and location is listed in Maine Table 2.
Plant growth was generally very vigorous at the northern
Aroostook County site. Yields were much higher at this site
than the other two. Early-dying problems were observed at
the central Maine and Aroostook Research Farm sites.
Plant stand equaled or exceeded 90% of targets for most
lines. Exceptions at Aroostook Research Farm were:
Katahdin (82%), Kennebec (79%), NorDonna (84%), and
Yukon Gold (76%). Exceptions at East Corinth were:
Katahdin (89%), Yukon Gold (84%), and AF1424-7
(87%). Exceptions at St. Agatha were: Katahdin (89%)
and NorDonna (86%).

Aroostook Research Farm NE184 Regional Potato Variety Trials. Many of the lines in the early and midseason tests died early due to early-dying disorder and/or other stresses. We received negligible rainfall over a onemonth period beginning July 10. Dark Red Norland, Superior, AF1424-7, and AF1565-12 were particularly early maturing in the early trial. Only Quaggy Joe exceeded Atlantic in total and U.S.#1 yields (Maine Table 3). U.S. #1 yields of Itasca, Monona, NorDonna, Superior, and AF1424-7 were significantly lower than Atlantic. Atlantic, Cherry Red, and AF1424-7 had relatively high specific gravities. All lines sized poorly; however, Atlantic, Chieftain, and Kennebec sized better than the remaining lines. Tubers of Atlantic, Cherry Red, Dark Red Norland, Quaggy Joe, Superior, and AF1437-1 were rated particularly attractive (Maine Table 4). There were relatively few external tuber defects in this trial and no hollow heart was detected. Atlantic, Itasca, Kennebec, Monona, Superior, and AF1424-7 had very good chip color scores. Although Quaggy Joe stood above the others in yield, none of the test lines performed exceptionally in this

In the mid-season test, AF1433-4 died very early. Niska and NY87 were also quite early maturing. None of the lines exceeded Atlantic in total or U.S.#1 yields (Maine Table 5). Kennebec, NorValley, B0564-8, NY87, and NY103 yields were equal to those of Atlantic, while Snowden, and AF1433-4 were very low yielding. All lines sized poorly; however, Kennebec sized better than the remaining lines. MaineChip, Niska, NorValley, Snowden, AF1433-4, and NY102 had particularly small tubers. Atlantic, MaineChip, Snowden, B0766-3, and NY102 specific gravities exceeded 1.080. There were relatively few external tuber defects and little hollow heart was detected in this trial (Maine Table 6). Scab was the major tuber defect in Kennebec. Misshapen tubers were prevalent in NorValley and NY103. Growth cracks were common in NY102. Most lines had significantly better chip color scores than Atlantic; however, Kennebec and B0564-8 scores were equal to Atlantic. Considering all attributes, the best performing lines in this test were NorValley, B0564-8, NY87, and NY103.

In the late maturity trial, Yukon Gold and B0856-4 senesced relatively early. Lines with particularly high U.S.#1 yields were AF1480-5, and AF1615-1 (Maine Table 7). AF1480-5 had the best tuber size for tablestock use. All of the test lines had specific gravities that equaled or exceeded those of Katahdin. Tubers of Yukon Gold, AF1480-5, and AF1615-1 were rated particularly attractive (Maine Table 8). Yukon Gold had more than 5% misshapen tubers. Relatively little hollow heart was

detected in the test. The best tablestock prospects in this test were AF1480-5 and AF1615-1.

In the russet or long-type variety test, growth was vigorous for most of the lines. B1004-8 had relatively small tops. Russet Burbank and Century Russet were late maturing, while the remainder had mid-season maturity. None of the lines produced total yields which exceeded Russet Burbank (Maine Table 7). Most of the test lines, produced U.S. #1 yields which were similar to those of Russet Burbank; however, B1004-8 and W1099Rus had significantly lower U.S. #1 yields. B9922-11 sized very well. Although most lines had lower specific gravities than Russet Burbank, Century Russet and B1004-8 were equal and B9922-11 had higher specific gravity. Tubers of Century Russet and B9922-11 were particularly attractive (Maine Table 8). W1099Rus had severe blackheart problems. Russet Norkotah and W1099Rus had significantly poorer chip color scores than Russet Burbank. Overall, Century Russet and B9922-11 were the best prospects in this trial.

Central Maine NE184 Regional Potato Variety Trial. Many of the lines in this test died early due to earlydying disorder and/or other stresses. This was especially true for Superior, AF1424-7, AF1433-4, and B0564-8. Katahdin, Kennebec, and Monona total yields were significantly higher than Atlantic (Maine Table 9). U.S.#1 vields of Katahdin, Kennebec, B0766-3, and NY102 were significantly higher than Atlantic. AF1424-7, AF1433-4, and B0564-9 were significantly lower yielding than Atlantic. Atlantic, MaineChip, Snowden, AF1424-7, B0766-3, and NY102 specific gravities exceeded 1.090. Scab was the major tuber defect in the trial and most lines had greater than 10% of yield affected by scab (Maine Table 10). Lines with less than 10% scab were Itasca, Snowden, Superior, and B0564-8. Atlantic, Katahdin, NorValley, and AF1424-7 had greater than 3% hollow heart out of 40 large tubers examined. MaineChip, Niska, NorValley, Snowden, AF1433-4, B0766-3, and NY87 had significantly better chip color scores than Atlantic. Considering all attributes, the best performing chipping lines in this test were Snowden, NorValley, B0766-3, NY87, and NY102.

Northern Aroostook County NE184 Regional Potato Variety Trials. Well-distributed rainfall and good soil conditions resulted in vigorous growth for most lines; however, AF1424-7 and AF1565-12 had relatively small tops. AF1565-12 was the earliest maturing line in the test, while Kennebec, AF1480-5, and AF1615-1 were quite late maturing. Lines with particularly high U.S.#1 yields were Chieftain, Dark Red Norland, Itasca, Kennebec, NorValley, Superior, AF1480-5, AF1615-1, B0811-13, and NY87 (Maine Table 11). Most of the test lines had specific gravities that equaled those of Katahdin; however, Chieftain, NorDonna, Quaggy Joe, Red Ruby, AF1437-1, AF1565-12, and B0811-13 were significantly lower. Most

lines sized well; however, NorValley, Snowden, AF1433-4, AF1565-12, B0856-4, and Red Ruby were smaller than most. Tubers of NorDonna, Dark Red Norland, AF1424-7, AF1480-5, B0811-13, NY87 and NY102 were rated particularly attractive (Maine Table 12). Katahdin, Cherry Red, AF1437-1, and NY103 had more than 5% scab. Quaggy Joe and AF1437-1 had more than 5% growth-cracked tubers. AF1480-5 and NY102 had greater than 5% hollow heart out of 40 large tubers examined. The best tablestock prospects in this test were Itasca, AF1615-1, B0811-13, and NY87.

In the russet or long-type variety test, growth was vigorous for most of the lines. Russet Burbank and Century Russet were very late maturing, while the remainder had mid-season maturity. Most of the test lines, produced yields which were similar to those of the standard lines; however, B1004-8 was significantly lower yielding (Maine Table 13). W1099Rus had particularly high U.S. #1 yields. B9922-11 and W1099Rus sized very well. B1004-8 and B9922-11 had higher specific gravity than Russet Burbank. Tubers of B9922-11 were particularly attractive (Maine Table 14). B9922-11 had significantly better chip color scores than Russet Burbank. Overall, W1099Rus and B9922-11 were the best prospects in this trial.

French Fry Processing from the 1996 Aroostook Research Farm Test. French fry color and texture of ten NE184 lines were evaluated under simulated processing conditions (Maine Table 15). Overall, none of the test lines produced french fries that were equal to Russet Burbank in quality. Krantz, Russet Burbank, AF1426-1, B9922-11, and W1099Rus had the best fry colors. Only B0493-8 had significantly poorer texture ratings than Russet Burbank.

Aroostook Research Farm Small-scale Storage Evaluations. Limited data on storage and processing characteristics were collected from 52 NE184 varieties and clones during the 1996-97 storage season (Maine Table 16). Chip colors from 50°F storage in February were acceptable for many lines with anticipated chipping potential. Lines with outstanding chip color from 50°F February storage were: AF1424-6 and AF1424-7 (early test); MaineChip, NorValley, AF1433-4, NY102, and W870 (medium trial); Niska (late trial). MaineChip, NY102, and W870 also produced very good chips directly from 45°F storage. None of the lines produced acceptable chips directly out of 38°F storage; however, MaineChip, Niska, Snowden, AF1424-7, AF1433-4, NY102, NY103, and W870 reconditioned well from 38°F storage.

After-cooking darkening scores are presented in Maine Table 16. Century Russet, Cherry Red, Krantz, Russet Norkotah, AF1455-9, AF1475-16, AF1565-12, ND2471-8, NY103, W870, and W1099Rus received poor color scores. Sloughing was observed in Atlantic, MaineChip, Snowden, and ND2471-8. Washed appearance

ratings were particularly outstanding for Cherry Red, Katahdin, Niska, Quaggy Joe, Red Ruby, Russet Burbank, Yukon Gold, B0493-8, B9922-11, and NY103.

Tuber dormancy was exceptionally short and early sprout growth was rapid for Krantz, NorValley, AF1433-4, AF1455-9, AF1475-16, AF1565-12, and B0564-9. Kennebec, Russet Burbank, AF1426-1, NY102, and NY103 required more than 195 days to reach the one-halfinch sprout stage. Selections with very low weight loss (2.5% or less) from 38°F storage were: Krantz, Russet Burbank, Yukon Gold, AF1433-4, and B9922-11. Selections with very low weight loss (9% or less) from 50°F storage were: Katahdin, Kennebec, NorDonna, Russet Burbank, Russet Norkotah, Yukon Gold, AF1426-1, ND2471-8, and NY103. Selections with high weight loss (18.5% or more) from 50°F storage were: Atlantic, Cherry Red, Dark Red Norland, MaineChip, NorValley, AF1433-4, AF1455-9, AF1475-16, AF1480-5, AF1481-4, AF1565-12, B0564-8, and NY87.

Promising Selections in the 1997 NE184 Regional Variety Trials. Selections that performed particularly well in the 1997 regional trials were AF1437-1 (early maturing, table line); Quaggy Joe (mid-season, tablestock round-white); B0811-13 (red-skinned, yellow-fleshed table line); NorValley, B0766-3 and NY102 (mid-season chipstock lines); NY87 and NY103 (mid-season table lines with some chipping potential); AF1615-1 (late-season table line); Century Russet (very late maturing, table russet); and B9922-11 (late maturing, dual-purpose, russet).

 $^1\mathrm{U.S.} \#1$ yield of late varieties = yield from diameter listed to 4", excluding external defects. U.S.#1 yield categories for the russet/proc. varieties = yield > 1-1/2", excluding external defects, and yield > 4 oz. tubers, excluding external defects, respectively.

tubers, excluding external defects, respectively. Inches between seedpieces noted within parentheses. 3 Size classes for late varieties: $1=1^{1/2}$ to $1^{7/8}$ "; $2=1^{7/8}$ to $2^{1/4}$ "; $3=2^{1/4}$ to $2^{1/2}$ "; $4=2^{1/2}$ to $3^{1/4}$ "; $5=3^{1/4}$ to 4^{11} ; 6=over 4^{11} . Size classes for russeted/processing varieties: 1=<4 oz; 2=4 to 8 oz.; 3=8 to 12 oz.; 4=12 to 16 oz.; 5= >16 oz.

Plant size, maturity at vinekill, tuber shape, tuber defects, hollow heart ratings, and chip colors for five late-maturing and six russeted/processing varieties grown at Presque Isle, Maine - 1997. (NE184 Regional Potato Variety Trials) Maine Table 8.

Tubers with scab were not excluded from U.S.#1 yield during 1997 because most scabby tubers had <5% of surface with the defect. $^1\mathrm{U.S.}$ #1 yield = yield 17% to 4" excluding external defects.

 3 Size classes: $1=1\frac{1}{2}$ to $1\frac{7}{8}$ "; $2=1\frac{7}{8}$ to $2\frac{1}{4}$ "; $3=2\frac{1}{4}$ to $2\frac{1}{2}$ "; $4=2\frac{1}{2}$ to $3\frac{1}{4}$ "; $5=3\frac{1}{4}$ to 4"; 6=over 4". ²Inches between seedpieces noted within parentheses.

Maine Table 10. Plant size, maturity at vinekill, tuber shape, tuber defects, hollow heart ratings, and chip color scores for 18 varieties and lines grown at East Corinth, Maine - 1997. (NE184 Regional Potato Variety Variety Trial)

¹See standard NE184 rating system for key to codes. ²Hollow heart rating equals the number of hollow tubers found per 40 large tubers cut and examined. ³Chip color from 50F -- Agtron M35 (higher values indicate lighter color): >60 acceptable; dr = vascular ring. The chipping date was December 8, 1997. Waller Duncan LSD (K=100) for chip color =

dr = dark

Chip color from 45 and 50F -- Agtron M35 (higher values indicate lighter color): >60 acceptable; All varieties had dark vascular ring defects in the chips. The chipping date was January 5, 1998. Waller Duncan LSD (K=100) *Hollow heart rating equals the number of hollow tubers found per 40 large tubers cut and examined. for chip color = 3 (for both storage temperatures). 'See standard NE184 rating system for key to codes.

Maine Table 15. French fry color and texture of selected potato clones and varieties under simulated processing conditions1. All varieties were grown at Presque Isle, Maine, during 1996.

blanched for 8 minutes at 170°F, par-fried at 375°F for 80 seconds, and quick frozen at -30°C in plastic bags. evaluation, samples were finish-fried at 360°F for 2-1/2 minutes on March 12, 1997, blotted dry with a paper Processing and evaluations were done by T. Work of the Department of Food Science, University of Maine, Orono, ME. All tuber samples were stored at 50°F, 85% R.H. from harvest until The slices were rinsed in cool water, such replications were processed on March 3, 1997 and held at -15°F until raw tuber slices were cut from each of ten tubers. towel, and cooled for 6 minutes. processing.

Color Grades are from USDA color standards chart #64-1, third edition.

graying; 4 = noGrayness indices represent weighted means derived from the following evaluation scale: 2 = moderate graying; 1 = intense graying. 3 = slight graying; Mealiness indices represent weighted means derived from the following evaluation scale: 5 = dry, mealy;

= french fries were irregular in color; dark blotches detracted from appearance of product; Be = Dark blotches on ends of many fries; Bc = Dark blotches in centers of many mealy. fries; Bl = general blotchy appearance of fries; Sh = Short fries from small and/or round tubers. 4 = mod. mealy, sl. moist; 3 = sl. mealy, mod. moist; 2 = soggy, not mealy; 1 = very soggy, not = uniform fried color; Ir Þ Comments:

Overall rating: quality rated better (+), not different (0), or poorer (-) than Russet Burbank.

Chip color from 38°F, 45°F, and 50°F storage, reconditioning potential, washed appearance ratings, days to sprout formation, and storage weight losses at 38% and 50% for 43 potato varieties grown at Presque Isle, Maine, during 1996 and stored during the 1996-1997 storage season. Maine Table 16.

'Stored at 38°F, 45°F, or 50°F, 85% R.H. from harvest until February 10 to March 5, 1997 Chip color scores are from an Agtron Model M-35 Process Analyzer (Agtron, Inc., Sparks, Nevada; calibrated with black disk Chips were crushed and reported values are means from four replicate Each sample was read three times and was thoroughly mixed between readings. Higher numbers = 0 and white disk "90" = 90).

Reconditioned samples were taken from 38% and placed at 70% for a 3-week period starting on January 22, See Agtron description under footnote #1.

Tubers were diced and then blanched for 5 min, cooled to 120°F, and then rated after 30 min. Higher indices indicate lighter color. Key to codes: sl-sloughing was Samples were stored at 45°F and 85% R.H. from harvest until March 21, 1997. They were then warmed to 65°F a defect in this sample; syl=slightly yellow; yl=yellow; pc=unusually poor overall color. with a Munsel Neutral Color Scale. for five days.

cracks, CS=common scab, SS=silver scurf, RS=russet scab, DR=dry rot, SR=soft rot, BS=black scurf, LE=enlarged in parentheses indicate subjective appearance of the sample using standard NE107 codes. Codes indicate major lenticles, B=bruises, BD=blackdot, PW=powdery scab, RA=red areas, PU=purple areas on seed end, SZ=small tuber 'Unreplicated samples weighing approximately 7500 grams were stored at 45°F and 85% R.H. until January 7, First number indicates % U.S. #1 grade tubers in sample. external defects as follows: M=misshapen, NR=nonuniform russeting, PC=poor color, SB=sunburn, 1996. Tubers were then washed and graded. size, FL=flat tubers, PR=pear shaped.

Tubers were stored at 45°F, 85% R.H.

Codes "s" or "r" indicate heavily sprouted or samples with more than Percentage sprout and weight loss following storage from harvest until March 31 to April 3, 1997, at indicated temperature and 85% R.H. spoiled tubers, respectively.

MAINE

Alvin F. Reeves, Garland S. Grounds, and Nena Huston.

University of Maine Potato Breeding Project

Objectives: The development of new potato varieties of three types:

1. high-yielding, round, white, fresh market varieties with good table qualities and resistance to scab; 2. round white chipping varieties with high dry matter and low sugars, especially after long term cold storage; and 3. russet varieties with high yield and high dry matter suitable for french fry processing and fresh market.

Seed and seedling production. A total of 57 parent plants were intercrossed in 140 different combinations (54 russet, 47 segregating for resistance to late blight, 51 with tablestock potential, and 14 with chipping potential) to produce 112,150 seeds. An additional 2,010,975 seeds were obtained from 69 field plantings. Greenhouse plantings of 60,500 true seeds yielded 23,031 seedlings from which 15,542 first tubers were harvested. Second tubers were harvested from 4,143 seedlings and planted in disease screening plots. Round tubers harvested in russet combinations were discarded; misshapen tubers were discarded from all combinations.

Seedling selection. A total of 613 (2.2%) new selections were saved from 27,791 single hills. From the 252 12-hill plots, 68 (27%) were saved for further testing. Fortytwo of 49 60-hill plots were selected, and 156 advanced selections were maintained and tested.

Disease tests. In cooperation with Drs. David Lambert, Gary Sewell, Bill Brodie, Robert Goth, Pete Weingartner, and Modesto Olanya, a number of selections were tested for disease resistances. All tests were inoculated either directly or on spreader rows within the plots.

Results were as follows: 3 of 8 were resistant to corky ring spot; 13/68 to acid scab; 38/105 to common scab; 27/71 to verticillium; 28/58 to golden nematode; 28/144 to late blight; 14/45 to leafroll; and 100/105 to net necrosis.

Physiological disorders. Additional tests for physiological disorders showed 11 of 52 resistant to hollow heart; 20/47 to blackspot bruising; and 15/31 to shatter bruising.

Chip tests. After processing in December and February, from five storage temperatures, fifteen entries had better average chip color than Monona (5.9): AF 1668-60 (4.1), AF 1424-7 (4.45), CS 7232-4 (4.5), Snowden (4.75), MaineChip (4.85), AF 1668-62 (4.9), AF 1433-4 (4.95), Somerset (5.0), ATX 85404-8 (5.05), NY 102 (5.1), ND 860-2 (5.35), NY 87 (5.4), NorValley (5.7), TX 1385-12Ru (5.7), and AF 1898-1 (5.8).

Commercial Trials. Along with MaineChip, Mainestay, Quaggy Joe and St.Johns, two numbered selections were grown on commercial farms in 1997: AF 1438-6 and AF 1481-4. They will be dropped because of growth cracks and low yields respectively.

Advanced Selections

Chipping selections:

MaineChip (AF 875-16; AF 186-2 x AF 84-4) was named in 1991. It is a high dry matter, cold-chipping variety, with yields of marketable size, specific gravity and chip color equal to Snowden. Commercial seed is not being produced even though one or two chip growers have had success with this variety.

AF 875-15, a sibling of MaineChip, has better yields than MaineChip and equal dry matter, but is not as good after cold storage. It is a good chipper from the field and does not show the heat necrosis that Atlantic does. Hollow heart is very rare, but growth cracks have been a problem in commercial fields.

AF 1668-60 (CS 7232-4 open pollinated) has excellent chip color from cold storage, with adequate gravity and yield. It is resistant to net necrosis and early maturing with moderate resistance to verticillium.

AF 1856-1 (CF 80247-1 x EB 8109-1) also has excellent chip color from storage and adequate gravity and yield. It is resistant to net necrosis, scab, and verticillium.

Round white table varieties:

Mainestay (AF 1060-2; AF 431-9 open pollinated) is slightly higher yielding than St.Johns, but is more susceptible to scab. It developed purple streaks in 1996, but this was not a problem in 1997. It is difficult to kill, and if dug green can give problems in storage. High yields and good size are its best qualities.

Quaggy Joe (AF 1470-17; CS 7589-8 x Portage) is a very high-yielding variety with good appearance and table quality. Problems seen so far have been hollow heart, purple streaks (not as many as in Mainestay), and pressure bruising. These problems were not prevalent in 1996 and 1997 commercial plantings.

St.Johns (AF 828-5; BR 6317-21 x CC 14-3a) is a late maturing variety with high yields and good disease reactions. It is resistant to golden nematode and the corky ring spot virus,

and does well all along the east coast. Two commercial growers have had trouble storing it, but yields and quality were good. It has a good washed appearance.

AF 1437-1 (AF 686-3 x B 7168-10) is a pretty round white with very high yields at early or mid-season harvest. Growth cracks may be a problem.

AF 1470-6 (CS 7589-8 x Portage) is very high-yielding at early harvest. It is resistant to net necrosis and verticillium. Low specific gravity and growth cracks may be problems.

AF 1565-12 (AF 303-5 x Sunrise) is a round white table variety with good size, appearance and yields. It is early maturing and resistant to golden nematode, verticillium and scab. Specific gravity is low and cooked texture is rated low, but overall ratings equal Superior.

AF 1569-2 (Portage x Sunrise) has high yields at early harvest in several locations. It is resistant to net necrosis, but susceptible to scab and growth cracks.

AF 1615-1 (SA 8211-6 x Sunrise) is a high-yielding medium-late maturing selection with resistance to net necrosis, golden nematode, verticillium, and scab. It has high specific gravity but does not give good chip color after storage.

Russets and Long Whites:

AF 1156-14 (Goldrus x Penobscot) has high yields and specific gravity with excellent french fry qualities. It is resistant to net necrosis, leafroll, and verticillium.

AF 1753-16 (CS 7981-7 x CF 7608-19) is a long russet with good shape, high yields, and fair processing quality.

Michigan Potato Variety Evaluations

D.S. Douches, R.W. Chase, K. Jastrzebski, R. Hammerschmidt, W. Kirk, C. Long, K. Walters and J. Coombs

The objectives of the evaluations are to identify superior varieties for fresh market or for processing and to develop recommendations for the growing of those varieties. The varieties were compared in groups according to the tuber type and skin color and to the advancement in selection. Each season, total and marketable yields, specific gravity, tuber appearance, incidence of external and internal defects, chip color (from field, 42 and 50 F storage), dormancy (at 50F), as well as susceptibilities to late blight, common scab, Fusarium dry rot, Erwinia soft rot, and blackspot bruising are determined.

Six field experiments were conducted at the Montcalm Research Farm in Entrican, MI. They were planted in randomized complete block design with four replications. The plots were 23 feet long and spacing between plants was 12 inches. Inter-row spacing was 34 inches. Supplemental irrigation was applied as needed.

Both round and long variety groups were harvested at two dates. They are referred to as the Date-of-Harvest trials. The other two field experiments were the North Central Regional and European trials. In each of these trials the yield was graded into four size classes, incidence of external and internal defects in > 3.25 in. diameter or 10 oz. potatoes were recorded, and samples for specific gravity, chipping, dormancy, disease tests, bruising, and cooking tests were taken. Chip quality was assessed on 25-tuber samples, taking two slices from each tuber. Chips were fried at 365°F. The color was measured visually with the SFA 1-5 color chart. Tuber samples were also stored at 42 or 50°F for chipprocessing out of storage in January and March.

Round White Varieties

Six varieties and 19 breeding lines were compared at two harvest dates. Atlantic, Snowden, Pike, and Onaway were used as checks. Entries were subject to early dying. As a result, the plot yields were below average. The results are presented in Tables 1 and 2. In the early harvest trial (95 days), NY101, Onaway, MSE228-9, MSE228-11, NY103, Atlantic, and Atlantic NewLeaf had the highest yields of the 25 entries. At the later harvest (127 days), NY101 and

Douches is an associate professor, Chase is a professor emeritus, Jastrzebski is a visiting scholar, Long is a research technician, and Walters and Coombs are graduate assistants in the Department of Crop and Soil Sciences, Michigan State University, East Lansing, MI 48824. Hammerschmidt is a professor in the Department of Botany and Plant Pathology, Michigan State University, East Lansing, MI 48824.

MSE228-11 were still the top yielders. The MSU advanced seedlings MSE018-1 and MSB107-1 were also high yielding. These two lines were also the top yielding MSU selections in the on-farm trials in 1997. Internal brown spot and hollow heart incidence were low within the trial, however vascular discoloration was more prevalent than in previous years.

Variety characteristics:

Atlantic NewLeaf - a selection from NatureMark which expresses the CryIII-Bt gene for beetle control. It performs similar to Atlantic.

NY103 - a chip-processing/fresh market selection from New York which has high yield potential, excellent internal quality, and smooth, bright appearance, but the specific gravity is too low for chip-processing. NY103 is equivalent to Atlantic for scab reaction. This selection has had excellent yield potential in on-farm trials. It is expected to be named by New York.

NY101 - a light-yellow-fleshed selection from New York. This line has an excellent shape, with netted tubers and very high yield potential. It is resistant to scab. In general, internal defects are low, but in 1995 we observed IBS in the oversize tubers.

Pike - an average yielding selection from New York. It chip-processes well and is resistant to scab similar to Superior. At times it has shown IBS in the tubers.

MSA091-1 - an MSU selection for chip-processing with scab resistance. Yields have been variable, but it has performed well in other states, and the late blight trials indicate a reduced susceptibility to late blight.

MSB076-2 - this MSU selection has high yield potential, has very high specific gravity, acceptable chip quality, and is resistant to scab. It is between Atlantic and Snowden in maturity, and we observed, in some instances, a tendency for hollow heart in oversize tubers. It has a large and upright vine type. This selection had the highest overall merit rating in the 1996 and 1997 North Central Regional Trials.

MSB107-1 - an MSU selection for the tablestock market. It is bright-skinned with large, round tubers with excellent internal quality. This selection performed well in grower trials in 1996 and 1997.

MSC103-2 - an MSU selection for the tablestock market. It performed well in the 1996 and 1997 on-farm trials. Its maturity is late, scab tolerance is intermediate, and it has reduced susceptibility to late blight.

MSE018-1 - an MSU chip-processing selection with high yield potential. It was an outstanding yielder in the 1997 onfarm trials. Specific gravity is high and it has a good general

appearance. Scab tolerance is intermediate and it has a reduced susceptibility to late blight. This line is targeted for the 1998 SFA Trials.

MSE221-1 - an MSU tablestock selection. It has high yield potential, but it did not perform well in the 1997 MRF trials due to early dying. General appearance is good and has strong resistance to scab.

MSE228-9 - an MSU selection for the tablestock/chip-processing market. Yield potential is above average, maturity is mid-season, and scab tolerance is good. It was in the 1997 on-farm trials.

MSE228-11 - an MSU selection for the tablestock/chip-processing market. It has high yield potential, mid-season maturity, and good scab tolerance. It was in the 1997 onfarm trials.

MSNT-1 - an MSU chip-processing selection. It has above average yield potential, excellent chip quality, and strong resistance to scab. It is targeted for the 1998 SFA trials.

Long Varieties

Five varieties and seven breeding lines were tested. Russet Burbank and Shepody were grown as check varieties. The first date-of-harvest trial was dug 120 days from planting rather than 95 days to give the trial greater time for tuber bulking. Most of the entries in the long-type trial were late maturing resulting in low yields and small tuber size at the first date-of-harvest (Table 3). At the second harvest on September 18 (136 days), yields for all entries had not changed due to potato early dying (Table 4). Yields were below average. Among the 12 long-type entries, Umatilla Russet (AO82611-7), Century Russet, and Shepody produced the highest yields at both harvest dates. Internal defects were not significant.

Variety characteristics:

Century Russet - a russet variety from Oregon/USDA-Aberdeen with high yield potential. It has excellent internal quality and bulks early despite a late vine maturity. It is susceptible to scab.

JS111-28 - provided by J.R. Simplot. JS111-28 has high yield potential with good general appearance, good russeting, and shallow eyes. It is a somaclonal derivative of Lemhi Russet selected for lower incidence of blackspot bruise. It is also highly scab resistant.

A7961-1 - is an USDA-Aberdeen entry with above average yield. It has uniform appearance, heavier russeting than Russet Burbank, and minimal internal defects. It can be used for frozen-processing.

Umatilla Russet (AO82611-7) - this selection was the top

performing line in 1997, but was below average in 1996. It is reported to have some resistance to early dying. Tuber shape is long but tuber width is narrow.

Newleaf Russet Burbank - a variety from NatureMark which expresses the Bt gene for beetle control. Yield was below average this year despite good vine growth.

MSE202-3Rus - an MSU selection with strong scab resistance. It has good appearance and may be suitable for tablestock or processing. Yield was low in 1997.

North Central Regional Trial

The North Central Trial is conducted in a wide range of environments, in 9 states to provide adaptability data for the release of new varieties from North Dakota, Minnesota, Wisconsin, and Michigan. Twelve breeding lines and seven varieties were tested in Michigan. The results are presented in Table 5. The range of yields was wide. The MSU selections, MSB076-2 and MSB106-7, performed well in 1996 and 1997. W1313, a Wisconsin seedling, had the highest yield but had over 50% of its oversize tubers with hollow heart and was the most bruise susceptible line in all the trials. The Minnesota selection, MN16489, had a high overall merit in the trial, but it has a blush skin which may limit its marketability. The North Dakota seedling, ND2676-10, has a nice appearance, some scab resistance, and a good chip score, but it had a below average yield and a specific gravity under the industry standards.

European/Yellow Trial

Five European varieties and advanced selections were tested along with three yellow-fleshed MSU seedlings. Snowden, Yukon Gold, Michigold, and Saginaw Gold were used as checks. The results are summarized in Table 6. Typically, most of the European selections and varieties are late to very-late in maturity, but in 1997, the vines died early and yields were down considerably. The best performing lines in 1997 were MSE222-5Y, MSE048-2Y, MSE149-5Y, and MSE226-4Y. MSE149-5Y is a light yellow-fleshed selection which will be advanced to the date-of-harvest round white trial in 1998 because of its processing potential. Pickouts were high in Latona, Obelix, Dali, MSA097-1Y, and MSA222-5Y.

Potato Scab Evaluation

Each year a replicated field trial at the MSU Soils Farm is conducted to assess resistance to common and pitted scab. The varieties are ranked on a 1-5 scale based upon a combined score for scab coverage and lesion severity. Usually examining one year's data does not indicate which varieties are resistant but it should begin to identify ones that can be classified as susceptible to scab. Our goal is to evaluate important advanced selections and varieties in the study at least three years to obtain a valid estimate of the

level of resistance in each line. We now have had four years of good scab trials (i.e. high levels of infection in susceptible lines).

Table 7A categorizes many of the varieties and advanced selections tested. Scab results are also found in the Trial Summaries (Tables 2, 4, 5, and 6). Table 7B summarizes the 1994-6 scab trial results for the lines in these trials. Many russet lines showed resistance to scab infection with Century Russet an exception to this trend. The MSU lines MSE192-8Rus and MSE202-3Rus, showed some resistance to scab in 1996 and 1997. Some round white tablestock clones have resistance such as Superior, Onaway, MSB040-3, MSE228-9, MSE228-11, and MSE221-1. Yellow-fleshed selections with resistance are NY101, MSE226-4Y, MSE226-5Y, MSC120-1Y, and MSA097-1Y. Scab resistance was also identified in the chip-processing clones Pike and MSU selections MSB076-2, MSA091-1, MSB073-2, MSNT-1, MSE230-6, MSF014-9, MSF313-3, and MSG227-2.

Blackspot Susceptibility

Increased evaluations of advanced seedlings and new varieties for their susceptibility to blackspot bruising has been implemented in the variety evaluation program. Check samples of 25 tubers were collected (a composite of 4 reps) from each cultivar at the time of grading. A second 25 tuber sample was similarly collected and was placed in a hexagon plywood drum and tumbled 10 times to provide a simulated bruise. Both samples were peeled in an abrasive peeler in October and individual tubers were assessed for the number of blackspot bruises on each potato. These data are shown in Tables 8A and 8B.

Table 8A summarizes the data for the samples receiving the simulated bruise and Table 8B, the check samples. The bruise data are represented in two ways: percentage of bruise free potatoes and average number of bruises per tuber. A high percentage of bruise-free potatoes is the desired goal; however, the numbers of blackspot bruises per potato is also important. Cultivars which show blackspot incidence of 3 or more spots per tuber from the simulated bruise are approaching the bruise-susceptible rating. In addition, the data is grouped by trial, since the bruise levels can vary between trials. These results become more meaningful when evaluated over 3 years which reflects different growing seasons and harvest conditions. Bruising was more severe in 1996 than in 1997 and 1995.

Late Blight Trial

In 1997 a late blight trial was conducted at the Muck Soils Research Farm. Over 175 entries were evaluated in replicated plots. The field was inoculated on July 22 and ratings were taken during July and August. Most lines were highly susceptible to the US-8 genotype of late blight. Lines with the least infection were AWN86514-1, B0767-2, B0718-3, and MSG274-3. The good agronomic qualities of

MSG274-3 makes this selection a strong candidate for commercial testing when enough seed is produced. Foliar susceptibility of all the lines tested against the US-8 genotype of late blight is summarized in Table 9.

Post-harvest Disease Evaluation: Fusarium Dry Rot

As part of the postharvest evaluation, resistance to *Fusarium sambucinum* (fusarium dry rot) was assessed by inoculating 8 whole tubers post-harvest from each line in the variety trials. The tubers were held at 20°C for approximately three weeks and then scored for dry rot infection depth and width. These data are summarized in Table 10. The clones in this table are grouped according to infection levels (low: < 8mm infection depth, moderate: 8-16mm infection depth, high: > 16mm infection depth). Few clones have low levels of infection. The best lines in this experiment were Snowden, B1004-8, MSG236-1, MSE030-4, and MSF105-10. The results of this experiment continue to support the low dry rot infection levels observed in Snowden and that the low infection level can be transmitted to progeny such as MSG236-1, MSE030-4, and MSF105-10.

^{*} Tuber samples were collected at harvest, graded, and placed in a six-sided plywood drum and rotated ten times to produce simulated bruising. Samples were abrasive-peeled and scored on October 23, 1997.

Table is presented in descending order of average number of spots per tuber.

Michigan Table 8B. 1997 BLACKSPOT BRUISE SUSCEPTIBILITY SAMPLES

Minnesota Potato Variety Evaluations

C.A. Thill, R.L. Wenkel, D.K. Wildung, V.A. Fritz, N.A. Anderson, R. K. Jones, D.W. Ragsdale, E.B. Radcliffe, and C.A. Longtine.

The major objectives of the University of Minnesota potato varietal breeding program are to: 1. Identify superior varieties for fresh market and for processing. 2. Screen and evaluate wild and cultivated *Solanum* germplasm useful in varietal improvement. 3. Initiate and explore new breeding methods. 4. Evaluate germplasm developed outside the Minnesota program for adaptation to Minnesota growing environments.

Field experiments were conducted at six Minnesota (Grand Rapids, Becker, Rosemount, Crookston, Hollandale, Long Prairie) and one North Dakota (Grand Forks) locations. Grand Rapids is located in North Central Minnesota, is non-irrigated, has a cool, short (100 days) growing season, and has acid fine sandy forested soils. Becker is located in Central Minnesota, is irrigated, has Hubbard sandy soils, and has a 140 day growing season. Rosemount is located 30 miles South of St. Paul, Minnesota, is nonirrigated, has silt loam soils, and a 140 day growing season. Crookston, Minnesota and Grand Forks. North Dakota are located in the Red River Valley of Minnesota and North Dakota. Both sites are nonirrigated with a 95-110 day growing season. Crookston has Fargo clay soils, while Grand Forks has heavy silt clay loamy soils. Hollandale is located in South Central Minnesota, has organic peat soils, and a 120 day growing season and Long Prairie is located in Central Minnesota, has course sand soils. and a 120 day growing season. Trials at Grand Rapids, Becker, Rosemount, and Crookston are located on Minnesota Agricultural Experiment Stations, while those at Hollandale and Long Prairie are located on grower fields. Trials at Grand Forks are located at the Potato Research Farm of the Red River Valley Potato Growers Association.

Thill is the potato breeder and an assistant professor, Wenkel is the potato project research scientist, Wildung is a professor, and Fritz is an associate professor in the Department of Horticultural Science, University of Minnesota, St. Paul, MN 55108. Anderson is a professor, and Jones is an associate professor in the Department of Plant Pathology. Ragsdale is a professor, Radcliffe is a professor, and Longtine is a graduate student in the Department of Entomology at the University of Minnesota.

Our use of these locations is partitioned such that Grand Rapids is the primary location for maintaining and increasing our selections, Rosemount is used for disease screening, and the remaining locations are used for multiple selection environments. Typically, newer seedling selections are planted at multiple locations without replications, while preliminary advanced and advanced selections are planted at multiple locations with replications. All seedlings are evaluated for plant growth and tuber characteristics, total and marketable yield, specific gravity, the incidence of internal and external defects, and susceptibility to late blight, verticillium wilt, and common scab.

Early Generations

The winter 1996-1997 crossing program (by Interim Potato Breeder Dr. Jan E. Backlund) produced 443 hybrid families. Approximately one-half of this effort (227 hybrid families) was placed on preserving and enhancing germplasm (Genetic Series) unique to the Minnesota Potato Breeding Program and developed by Dr. Florian Lauer. The Genetic Series has both diploid and tetraploid clones developed for: 1) high protein, 17 clones; 2) chipping potential, 31 clones; 3) 2n pollen, 22 clones; 4) GPA resistance, 14 clones; 5) CPB resistance, 21 clones; 6) *S. Andigena*, 19 clones; and 7) cold chipping, 10 clones. The remaining 216 hybrids emphasized reds (50%), russets (30%), and round whites (20%) for fresh market and processing potential.

New seedling progenies (first field generation 1997) were sown and transplanted to the field at Grand Rapids, MN. Of the 35,000 seedlings transplanted, 10,000 from 206 hybrid families were selected and will be planted at Crookston, MN as 4-hill plots (second field generation) in 1998. Traditionally, selection intensity among the first year seedling progenies is mild due to being planted from transplants and having an 80-90 day growing season. The Crookston environment is severe in that it is characterized by heavy clay soils, is non-irrigated, and water drains slowly; which, tends to result in tubers exhibiting malformation and/or other defects. The selection intensity at Crookston is high; approximately 250-500 clones will be advanced. In 1997 at Crookston, 254 clones were selected for advancement from approximately 32,000 4-hill plots.

New hybrid families are being generated in our winter 1998 crossing program. Emphasis is being placed on:

- 1) Developing high yielding, high quality fresh and processing reds (30%), longs (25%), and round whites (45%).
- Broadening the genetic base of our parent population by using clones sourced nationally and internationally.
- 3) Evaluating and introgressing wild species germplasm for resistance to CPB, late blight, verticillium wilt, common scab, silver scurf, and cold-sweetening.

Intermediate Generations

Four hundred ninety four clones were evaluated at four locations, Becker, Crookston, Grand Rapids, and Grand Forks. This population can be partitioned into two groups 1) older, and 2) newer selections. The older selections (146 clones) were planted in 2 replications of 20-hill plots, while the newer selections (348 clones) were planted as non-replicated 20-hill plots.

Testing is continuing for total yield, US#1 yield, specific gravity, processing traits, agronomic and horticultural characteristics, and disease resistance. Several clones have shown moderate resistance to common scab, and verticillium wilt; none showed resistance to late blight. We expect that about one-third of these selections will be retained.

Preliminary Advanced Seedling Trials (Preliminary Replicated Trials)

Twenty-three clones were evaluated in Preliminary Replicated Trials at 3 locations, Becker (Table 1), Crookston (Table 2), and Grand Forks (Table 3). Single-row plots were planted in a Randomized Complete Block Design (RCBD) with 2 replications of 20 hills. Seed piece spacing was 12" within row and 36" between rows. Standard crop management practices were used.

Reds

Fourteen Minnesota seedling selections were compared to varieties Dark Red Norland, and Red Pontiac (Tables 1 to 4). Desired characteristics include early and late maturity, bright red colored skin that lacks fading, good skin set, and high yield. Yields tended to be highest at Becker and ranged from 239 – 677 total cwt/A. Yields were lowest at Grand Forks (21 - 152 total cwt/A). These results

can be expected; growing conditions at Grand Forks were unfavorably wet and Becker was excellent.

Twelve Minnesota seedlings at Becker, eleven at Crookston, and five at Grand Forks yielded higher than Dark Red Norland. Minnesota seedlings MN 17993, MN18370, MN18768, and MN18808 had favorable yields, good appearance ratings, and low incidence of tuber defects across the three locations. Moreover, they tended to have twice the yield of Dark Red Norland at Grand Forks.

Russet / Long

Four Minnesota seedling selections were evaluated (Tables 1 to 4). Yields were highest at Becker and lowest at Grand Forks. The seedlings performed differently across locations and specific gravity and tuber appearance are concerns. Selection NM 18710 had high yields and favorable appearance ratings, but low specific gravity. This clone will be evaluated for fresh market potential.

Round Whites

Two Minnesota seedlings were compared to Norchip (Tables 1 to 4). Though the yields at Becker were favorably high, none will be continued due to lacking desirable tuber type.

Advanced Seedling Trials (Replicated Yield Trials)

Twenty-nine clones were evaluated in Replicated Yield Trials in five environments. Single-row plots were planted in a Randomized Complete Block Design (RCBD) with 2 replications of 20 hills. One location, Becker, Minnesota had two harvest dates, an early (Table 5, 111 days) and a late (Table 6, 146 days). The other locations were Grand Forks (Table 7), Hollandale (Table 8), and Long Prairie (Table 9). Seed piece spacing was 12" within row and 36" between rows. Standard crop management practices were used.

Reds

Eight Minnesota and one Colorado seedling selections were compared to check varieties Dark Red Norland, Red LaSoda, and Red Pontiac (Tables 5 – 10). Yields tended to be highest at Becker (late) and Long Prairie, intermediate at Becker (early) and Hollandale, and lowest at Grand Forks. Two Minnesota seedlings MN 17922 (250 cwt/A) and MN

18365 (257 cwt/A) yielded comparable to Dark Red Norland (257 cwt/A) at the early Becker harvest and all nine seedlings were higher yielding than Dark Red Norland at the Becker late harvest. CO86218-2 had deep dark red skin color and was very attractive at Becker (late). Minnesota seedlings MN 17572, MN 17922, and MN 18365 had exceptional performance across locations.

Russet / Long

Two Minnesota seedlings were compared to Goldrush, Russet Burbank, and Russet Norkotah (Tables 5 – 10). Both MN 16478 and MN 18142 performed well at all locations with higher yields than cultivars at all but one location. Tuber appearance ratings are high and MN 16478 tends to be blockier in shape. Vascular discoloration seems to be one limiting internal quality.

Round Whites

Six Minnesota seedlings and one Colorado selection of a Beltsville seedling were compared to Atlantic, Itasca, Latona, and Norchip (Tables 5-10). Yields were generally as high or greater than Atlantic and Norchip. The incidence of internal defects, in general was high, but comparable to Atlantic. The specific gravity of these clones may not be high enough for efficient chip processing.

North Central Regional Potato Variety Trial

North Central breeding programs have developed many of the most widely grown varieties in the US. These account for 5 of the top 10 leading varieties and cover the breadth of market types: fresh and processing russets, reds, and round-white chippers. Our regional meeting (NCR-84) plays an important role in this success by providing a forum for collaborative research, regional varietal testing, and by facilitating exchange of germplasm and research ideas.

As part of this cooperative effort North Central potato breeders enter their most advanced seedling selections in regional trials located at eight US and two Canadian locations. Minnesota's potato breeding program entered three clones MN 16180, MN 16489, and MN16966 in 1997. Results from this trial at Becker are presented (Table 11). The three Minnesota selections were the highest yielding clones in the round white market class. Specific gravity was low and internal defects equal or lower than Atlantic,

Norchip, or Snowden. Maturity is medium-late and overall appearance ratings were favorable. Across all locations MN 16966 and MN 16489 were 1st and 2nd, respectively for total yield and MN 16489 and MN 16180 ranked 1st and 4th, respectively for general merit.

In 1998, four Minnesota clones will be entered; MN 16478, russet; MN 16966, light russet; MN 17572, red; and MN 17922, red.

Disease Screening

Scab

Each year Minnesota selections, germplasm used for special characteristics in breeding, and cultivars are assessed for resistance to common scab at Becker and Grand Rapids. Clones are evaluated for scab lesion type (0 = no scab to 5 = deep pitted scab), and scab coverage (T = trace to H = heavy). Presented in Table 12 are the scab evaluations of the 438 clones entered at Becker in 1997. Many of our promising selections are moderately resistant.

Late Blight

In 1997 our late blight trial was conducted at Rosemount. More than 500 Minnesota seedlings were evaluated in un-replicated plots, while advanced seedlings and cultivars from other US breeding programs and European varieties were evaluated from a replicated trial. The trial was planted June 9 and inoculated August 14 with the A2, US8 genotype. Foliar readings were done on weekly intervals from August 25 to September 17. A summary of the results from European varieties and clones from other US breeding programs are presented (Table 13). None of the Minnesota material showed resistance to late blight. Clones AWN 86514-2, B0692-4, B0718-3, and B767-2 had the highest levels of foliar resistance.

Verticillium Wilt

In 1997 our verticillium wilt resistance evaluations were conducted at Grand Forks. Minnesota selections and other breeding germplasm are evaluated for resistance to *V. dahliae* (Table 14a) and *V. albo-atrum* (Table 14b). Resistant selections have been identified and are being used in breeding. Germplasm showing field resistance are being evaluated in the laboratory for resistance using an assay to quantify vascular colonization.

Potato Leafhopper Resistance

Twenty-nine wild Solanum species (116 accessions) were screened for resistance to potato leafhopper at the University of Minnesota Agricultural Experiment Station, Rosemount. To facilitate subsequent utilization as breeding material, emphasis was placed on screening potato germplasm having good tuberization potential and known to be capable of producing 2n pollen. Two sources were identified: 1) twenty accessions representing 10 wild species identified as being capable of producing 2n gametes; and 2) accessions from species with dense trichomes which also possess good tuberization characteristics when introgressed into existing cultivars. Additional accessions possessing a range of leaf hair or trichome length and density were chosen from species data provided by Dr. David Spooner (University of Wisconsin). Plants were also screened for resistance to Colorado potato beetle and plant vigor. Several

species combined plant vigor and resistance to potato leafhopper and Colorado potato beetle (Table 15), e.g., S. agrinionifolium, S. berthaultii, S. candolleanum, S. chacoense, S. kurtzianum and S. pampasense. Germplasm having good tuberization potential and known to be capable of producing 2n pollen, e.g., S. canasense, S. gourlayi, S. vernei, and S verrucossum had one-third to one-half as many potato leafhoppers as Russet Burbank

Means followed by the same letter within columns are not significantly different (P > 0.05); REGW-F test.

Plot design: RCBD, 4 reps, 7 plants/rep.

^dAccessions were combined within species.

^aNymphs and adults were combined following vacuum sampling of plants for PLH.

^bCPB defoliation score: 1 = susceptible and 9 = resistant.

^cSize score: 1 = smallest plants and 9 = largest plants.

Nebraska Potato Variety Trials Alexander D. Pavlista

Extension Potato Specialist University of Nebraska Panhandle Research and Extension Center 4502 Avenue I Scottsbluff, NE 69361

Introduction

In 1997, trials were conducted at Imperial, Kearney, O'Neill, and Scottsbluff. All entries were planted at Imperial and Scottsbluff, the latter also had three additional entries, while white-skinned entries were planted at Kearney and the other entries at O'Neill. There were 18 white-skinned (20 in Scottsbluff), 11 russet, 6 red (7 in Scottsbluff), and 1 yellow entries. Nebraska participated in the North Central Regional (NCR) trial having 19 entries. This trial was conducted at the Panhandle Research and Extension Center (PREC) in Scottsbluff.

Materials, Methods and Conditions

Soils were sandy loams; pHs were from 5.6 to 7.9, and organic matter content was between 1 and 2.5%. The ranges of major fertilizers were 180 to 330 lb N/ac, 90 to 180 lb P/ac, 0 to 350 lb K/ac and 0 to 80 lb S/ac. At some locations, boron, magnesium and/or zinc were also added. Seed pieces were cut, treated with TOPS MZ and stored for seven to 30 days at 55 F. Growers used their conventional practices. Insecticides were Thimet applied at planting and, depending on location, post-emergence applications of Asana, Monitor, Provado, and DiPel. Depending on location, Turbo, Prowl plus Lexone were applied pre-emergence or at hilling and Poast was applied post-emergence for grasses. At Scottsbluff, no preemergence herbicide was applied; two applications of Eptam plus Matrix were applied in June. Besides the seed treatment, Bravo, Dithane, Curzate M-8 were used for early and late blight prevention. No fungicides were used at Scottsbluff. Vines were desiccated with Diquat. In Scottsbluff, vines were allowed to die from late blight in order to take susceptibility readings.

The trial design was 20-60 foot strip plots from which a section was harvested. The North Central Regional Trial was conducted as three replicate plots of 20 seedpieces. The key growth dates for all trials are listed in Table 1. Trials were conducted under overhead sprinkler irrigation. Rainfall and relative humidity tended to be below normal except mid-July to mid-August and, in most locations at the end of May. Temperature was normal.

Yield data were taken on tubers under 1% in, between 1% and 4 in, and over 4 in size. Within two weeks after harvest, tuber defects and specific gravities on 1% to 4-

inch tubers were determined visually and using a hydrometer, respectively. Fry color of entries were measured using the SFA/PC color chart. Color was determined following curing.

Nebraska Table 1. Key dates for each trial in 1997.

Results and Discussion

YIELDS: The highest yields (>400 cwt/a average of three locations) were white entries: Snowden, CalWhite, ATX85404-8, Ptarmigam¹ and MN15622; russet entries: AO82-611-7 and Russet Norkotah St. #8²; red entries: Ruby Gold¹ and Dark Red Norland, and Yukon Gold¹.

SPECIFIC GRAVITY: Most white entries had average specific gravities above 1.080. W1313 averaged the highest (1.092). The high yielders, CalWhite and Ptarmigam, had relatively very low specific gravities. Among russet entries, most had a specific gravity above 1.075 with AO82-611-7 having the highest (1.084). The specific gravity among the red entries was scattered; NE8664 averaged highest (1.082). Yukon Gold's gravity was 1.081.

COOKING COLOR: Light colored chips (< 2 on chart) were produced from most white entries. Unacceptable color was observed from AF875-15, Shurchip, Ptarmigam, and CalWhite. (The latter two were high yielders.) CalWhite is probably best in the long-white, fresh market. Most russet entries' fry color was below 3. Russet Norkotah (regular) and W1151rus fried darker than Russet Burbank and were unacceptable.

TUBER DEFECTS: Entries in which the tubers had the following defects were:

Off-Shape (>10% @ 2 sites): Russet Burbank and Russet Norkotah strain #3 (CO);

Common Scab (>10% @ Scottsbluff): Atlantic, AF875-15, NE8644, and W1313 in Kearney; W1151rus; Redsen and NE8664, and Yukon Gold.

Black Scurf (>10% @ 2 sites): AF1433-4, ATX85404-8, NE8644, NE8810, and W1313; Russet Burbank and Russet Norkotah strains #3 and #8, and Yukon Gold. Hollow Heart: Nearly all entries had less than 5%; NE8644 had 8% at Imperial.

Vascular Discoloration (>9% @ 1 site): Brador¹, CalWhite, Russet Burbank, Russet Norkotah strain #3, and NE8242.

Sprouting (>10% @ Imperial): CalWhite, Shurchip, AF875-15, and MN15622.

Greening (>9% @ Kearney): NE8810, NE8812 and NE8813.

LATE BLIGHT SUSCEPTIBILITY (Table 5): Brador is the only entry that showed tolerance of late blight. This cultivar was entered due to the recommendation of the breeder in New Brunswick, Canada, as being resistant to late blight and a standard for comparison. Those entries that seemed least susceptible to late blight were CalWhite, Snowden, AF1433-4, W1313, and Allegany among the other white entries. Among russets, Russet Nugget and Russet Norkotah #3 strain were least susceptible. Temagami, a Canadian red entry, also showed less susceptibility than other entries. Note that the late blight readings were visual plot estimates.

In the North Central Trial (Table 9), entries with the least late blight susceptibility were Snowden, MSB073-2 and MSB076-2, all white chippers. The MSB entries are from Michigan. Other North Central Trial data from Nebraska are in Tables 7 and 8.

NEW JERSEY

Melvin R. Henninger

Introduction

Trials were conducted at the Rutgers Agricultural Research & Extension Center in Upper Deerfield Township and The Snyder Research & Extension Farm near Pittstown. All plots were 21' long and 3' wide. Seedpieces were spaced at 9" for round types and 12" for long types. At the Rutgers Ag Res & Ext location, part of the nitrogen and all of the P₂O₄ and K₂O were applied before planting and disked in. Additional nitrogen was topdressed 5 weeks after planting to bring the total up to 150 lb/A. At the Snyder Farm 1000 lbs./A of 15-15-15 was broadcast and disked in before planting. At both sites, Dual and Sencor were applied shortly after planting and Matrex and Lexone after hilling.

The Upper Deerfield plots were harvested with a single-row mount commercial harvester modified for bagging. No attempt was made to recover any lost tubers caused by normal harvester operation. All plots were sized with a spool sizer and specific gravities were determined by the weight in air and water method. Chip color was done by Mr. Steve Molnar of Wise Foods five days after harvest.

The Snyder Farm plots were harvested with a single-row commercial potato digger. Round types were sized with a spool sizer, the long types were sized by weight, and specific gravities were determined by the weight in air and water method.

In 1997, planting was normal and growing conditions were cool early, hot and dry after June 1st. Rainfall was supplemented by many irrigations. At the Snyder Farm location in northern New Jersey, conditions were dry but somewhat cool and growth was very good. Ozone levels were high in early July and some varieties were damaged. Insects and diseases were not a limiting factor to growth.

To simplify above information, trade names of some products are used. No endorsement is intended, nor is criticism implied of similar products not named.

New York

R.L. Plaisted, B.B. Brodie, D.E. Halseth, S.A. Slack, W.M. Tingey and K.D. Paddock

Early Generations

The crossing program produced 87 round white combinations with chipping and tablestock potential, 3 red combinations, 39 trichome hybrids, 23 segregating for resistance to late and 39 combinations segregating for resistance to two or more races of Globodera rostochiensis.

Seeds produced in 1995 (V's) were sown and the seedlings were transplanted to six inch pots. Four tubers were saved from each, after selecting for tuber color in the trichome and red progenies. There were 8283 round whites, 3678 <u>Globodera</u> race Ro2 resistant, 1997 with late blight resistance and 4340 with trichomes.

The four hill seedling populations (U's) started with 7385 round whites. At harvest 461 were selected for tuber type, then stored at 45° for one month prior to chipping and testing for resistance to the golden nematode. The 756 reds were selected for shape and tuber color, then golden nematode resistance, and 27 saved. There were 356 selections from 3601 segregating for resistance to the Ro2 race of golden nematode.

The 3804 trichome clones were selected for tuber type at harvest, then for chip color and resistance to the golden nematode. 205 were saved. The 2092 clones bred for resistance to Pratylenchus penetrans produced 126 selections.

The third year generation (T's) consisted of 1289 clones in 24 hill plots. At harvest 345 were saved and the following winter evaluations were made for chip color, specific gravity and golden nematode resistance.

Intermediate Generations

The fourth year selections (S's) were grown as 100 hill plots for seed production and selection and in two row by 20-foot plots for observation and chip samples. From the 345 that were grown, 47 have survived the fall selection and post harvest tests.

The fifth generation (R's) were grown in 400 hill seed plots and a replicated yield trial. The 17 at this stage of selection were reduced to 6 and are being introduced to virus—free in vitro production. All are round white clones.

Advanced Generations

A summary of the performance of the most advanced clones is as follows:

NY101 = K7-1 = Steuben x Norwis (1986).Mid-late season tablestock. Pale yellow flesh. Scurfy skin. Exceptionally high yields of large round tubers. Yield at Mt. Pleasant and Ellis Hollow for seven seasons has been 110% of Atlantic. At four sites in 1995, NY101 yielded 114% of Atlantic and at two sites was 151% of Katahdin. At four sites in 1996, the yield was 124% of Atlantic. At six sites in 1997, the yield was 123% of Atlantic. The average for 14 trials was 121% of Atlantic. Early sizing. Large tuber size. Very round. Very few pickouts. Internal necrosis has been observed frequently in Long Island trials, in two Ithaca trials in 1995 and in the Harford trial in 1997. Scab resistance like Superior. Specific gravity like Katahdin. Very nice vine growth and appearance. Resistant to nematode. The excellent yield, tuber shape, and eating quality of this clone merit its evaluation for markets which will accept the pale yellow flesh.

NY103 = K88-24 = Steuben x (Neotbr x tbr) (1986). Midseason table and chipstock. Yield of US #1 relative to Atlantic was 91% at five upstate sites in 1993 and was 118% at seven

upstate sites in 1994, 114% at six sites in 1995, 110% at six sites in 1996, and 96% at six sites in 1997. The average of 30 tests was In four years at Riverhead, NY103 vielded 108% of Katahdin. Outstanding tuber appearance. Very bright, blemish-free skin. Round shape. Shallow eyes. Medium sized tubers. Almost free of pickouts and internal defects. Scab resistance like Monona. Tuber dormancy seven weeks longer than Katahdin and Monona. Nice vine type. Specific gravity is .013 less than Atlantic (33 trials, 5 years). Chip color is like Monona. In 1994, after 450 storage the Agtron for NY103 was 54 compared with 55 for Monona. In 1995, the Agtron for NY103 and Snowden were both 60. In 1996, the Agtron score for NY103 was 49, Monona was 40. and Snowden was 53. Resistant to the golden nematode, PVX, and PVY. May not perform as well on muck soils as upland soils. This is a unique clone with exceptional tablestock and good chipping qualities, deserving special attention.

NY110 = M28-3 = Pike x Q155-3 (1988).Tablestock. Late season maturity, early sizing. Full season marketable yields in upstate trials in four years have been 91% of Atlantic. On Long Island full season yields in three years have been 114% of Katahdin. Early season yields in four years have been 115% of Superior. It has been exceptionally free of internal defects at Riverhead and upstate. Tuber size is very large. Bright skin. Specific gravity in six years has been .011 less than Atlantic. Scab resistance is similar to Monona. Tuber dormancy is five weeks longer than Atlantic. The bright skin, freedom from internal defects, and early sizing make this of particular interest for Long Island. Medium plant size, rugose leaflets. Resistant to the golden nematode.

NY112 (P7-19) = Atlantic x Q155-3 (1990) Late maturity chipstock. Very scurfy skin texture, but attractive round shape. Outstanding yield: marketable yields in four years at Ithaca 115% of Atlantic. In five upstate trials in 1996, the marketable yield was 128% of Atlantic. In six upstate trials in 1997, the marketable yield was 117% of Atlantic. In two years, the early season yield was 106% of Superior. Good chip color from 45° storage in 1996. Specific gravity is .007 less than Atlantic (14 trials), .012 greater than Monona. Tuber size is like Atlantic. Few pickouts, but hollow heart may be a problem in the larger tubers. Large vines. White flowers. Golden nematode resistant. Scab resistance between Monona and Superior.

NY115 (P23-31) = Pike x NY88 (1990)Medium maturity chipstock and tablestock. Large tuber size. Early sizing. Attractive, very bright tubers. Marketable yields in upstate trials in four years were 93% of Atlantic. Early harvest yields in two years were 108% of Superior. Few pickouts and internal defects. Scab resistance like Atlantic. Golden nematode resistant. White flowers. Attractive vine. Specific gravity is .010 less than Atlantic. Outstanding chip color in 1995 and 1996. The tuber appearance and chip color have been very favorable, but the yield has been marginal, so special spacing and fertilizer trials are needed

 $NY118 (P49-19R) = D191-103 \times Chieftain$ (1990). Late season, light red tablestock. Marketable yields at Ellis Hollow and Harford in 1996 and 1997 were 91% of Chieftain. At Freeville in 1997, the yield was 101% of Chieftain. Tuber set and size of NY118 and Chieftain are similar. Few misshapen tubers and free of internal defects. Attractive, oval shape. Skin is slightly textured and resists skinning. Eyes are sparse and very shallow. The intensity of color is similar to that of Chieftain. Flesh color is bright white before and after boiling. Specific gravity is .005 less than Chieftain. Tuber dormancy is 4 weeks longer than Chieftain. Better scab resistance than Chieftain. Resistant to race Rol of the golden nematode. The overall appearance of

this clone merits its evaluation as an alternative to Chieftain.

 $NY119 (P63-1) = E57-13 \times NY91 (1990)$ Midseason chipstock. Marketable yields at Ellis Hollow and Harford in 1996 and 1997 were 98% of Atlantic. In three other NY trials in 1997 the yield was 90% of Atlantic. Early harvest yield in 1997 was 103% of Superior. Tuber set is greater than Atlantic and tuber size in less. Few pickouts, but hollow heart has been a problem in 6 of 10 trials. Specific gravity is .002 greater than Atlantic (9 trials). Chip color from 45° storage has been brighter than Monona. Slight after cooking darkening and severe sloughing after boiling. Tuber dormancy 5 weeks longer than Atlantic. Good vine type. Scab resistance like Superior. Resistant to race Ro1 of golden nematode. Susceptible to midseason Sencor application. Looks promising for chipstock if hollow heart can be controlled.

 $NY120 (Q8-2) = Kanona \times AF186-2 (1991)$ Mid-late season chipstock. Marketable yields at Ellis Hollow and Harford in 1996 and 1997 were 104% of Atlantic. In three other NY trials in 1997, the yield was 123% of Atlantic. Early harvest yield in 1997 was 106% of Superior. In three trials in 1997, Q8-2 averaged 6.3 tubers per foot compared to 7.3 for Atlantic and weighed 7.8 oz. compared to 6.7 for Atlantic. A small proportion of misshapen pickouts. Generally free of internal necrosis and hollow heart. Very nice vine type. Tubers have a very scurfy skin texture. Specific gravity is .002 less than Atlantic (9 trials). Chip color from 45° has been better than Monona. Tuber dormancy has been two weeks shorter than Atlantic. Scab resistance has been like that of Monona. Resistant to race Rol of the golden nematode. Looks promising for chipstock. Needs spacing and fertility trials in 1998. Limited nitrogen and closer spacing may improve yield, size and chip color.

NY121 (Q237-25) = N43-288 x E74-7 (1991) Mid-late season tablestock. Bright white skin. This clone has resistance to late blight, and to four races of the cyst nematode Ro1, Ro2, P4A, and P5A. It appears to be resistant to PVY and scab. In a single trial in Ellis Hollow in 1997 it produced a marketable yield 87% of Atlantic. Tuber size is smaller than Atlantic. It had no internal or external defects. The specific gravity was .007 less than Atlantic. Scab reaction is like Monona.

NY122 (R3-14) N42-10 x Pratyl Bulk (1992) Medium maturity tablestock. Bright white skin. Oblong shape. This clone is resistant to four races of the cyst nematode, Ro1, Ro2, P4A, and P5A. It may be resistant to PVY. In a single trial in Ellis Hollow in 1997, it produced a marketable yield 103% of Atlantic. Tuber size was similar to Atlantic. The loss from misshapen tubers was greater than Atlantic, but it had fewer internal defects. The specific gravity was .016 less than Atlantic. This clone has potential use by tabelstock growers who need to grow an Ro2 resistant variety. Scab reaction is similar to Katahin.

 $NY123 (R127-19) = M504-2 \times L227-243$ (1992). Medium-late maturity tablestock. Bright white skin. This clone combines good trichome features with attractive tuber shape and good agronomic performance. In a single trial in Ellis Hollow in 1997, it produced a marketable yield 99% of Atlantic. There were few pickouts and no internal defects. The specific gravity is .005 less than Atlantic. At Freeville, in plots protected by insecticide, NY123 yielded 95% of Allegany. In adjacent plots without protection from insecticides NY123 suffered only 14% yield reduction whereas Allegany suffered 70% yield reduction. Three year's data show only 11% yield reduction due to Colorado potato beetles in unprotected plots and no visible leaf hopper damage. This clone is resistant to race Rol of the golden nematode and probably to PVY. Scab resistance is like Atlantic.

Long Island, New York

J. B. Sieczka, D. M. Gergela, R. C. Neese, M. L. Masierowska and D. D. Moyer

Introduction: Experiments conducted in 1997 are part of an ongoing program evaluating promising potato clones under Long Island conditions. Fifty-three potato clones were evaluated in replicated experiments conducted at the Long Island Horticultural Research Laboratory (LIHRL). In addition, fifty-eight clones were included in an observation trial.

Methods: The randomized complete block design with four replications was used in all the experiments. Variety plot size was 2 rows by 12 feet. Fertilizer was applied at a rate of 1,000 lbs/A of 10-20-20 in bands at time of planting (4/15-16/97). additional 60 lbs N/A were applied when plants were 4 to 6 inches tall. Vines in the early experiment were rated for maturity on 8/16/97, plants were roto-cut on 8/11/97 and yield data were collected on 8/20/97. Vines in other variety evaluation experiments were vine killed on 9/12/97 and were harvested on 9/23/97. Specific gravity was determined by the hydrometer method. Internal defects were determined on 10 tubers per replication in the 3.25 to 4 inch or 12 to 16 oz. categories for round and russet experiments, respectively. Tables summarize maturity ratings, tuber appearance and shape.

Experiments to determine the effect of nitrogen rate and spacing on vigor and yield of NY103, NY109 and B9922-11 were established on 4/23/97. Plot size was 3 rows x 15 feet long with the center row x 12 feet used for data. All plots were fertilized at a rate of 1,000 lbs/A of 10-20-20 in bands at planting. Sidedress nitrogen treatments of 0, 50, and 100 lbs/A were applied on 6/4/97. Spacing treatments were 6 and 9 inches. Plants were vine killed on 9/12/97 and harvested on 10/7/97.

Early White-skinned Clones: There were no significant differences in total yield and marketable yield between Andover, Superior N1 (standard Superior obtained from Nature Mark), AF1470-6, AF1475-20, Reba (NY87), NY109 and NY110 (Tables 2 & 3). The best appearing lines were Andover, Reba, NY109, and NY110. Tubers of AF1475-20 and NY110 had the highest specific gravity. Tubers of AF1437-1 and AF1470-6 had low specific gravity. Internal necrosis was observed in tubers of AF1470-6, AF1475-20 and NY109.

NE184 White-skinned Clones: The marketable yields of Katahdin, Atlantic and B0766-3 were not significantly different from each other (Tables 4 & 5). NY103 tubers were the most attractive and AF1615-12 and Reba tubers had good appearance. Specific gravity of Atlantic and NY102 tubers was high. Internal defects were severe in Atlantic, Yukon Gold, and AF1480-5.

White-Skinned University of Maine and USDA Seedlings: AF1714-2 and B1240-14 produced marketable yields significantly lower than Katahdin (Tables 6 & 7). All other entries produced marketable yields not significantly different from Katahdin. The specific gravity of B1240-14 tubers was considerably higher than the others. The best looking lines were B0564-9, B1240-12 and B1429A-6. Severe internal defects were noted in tubers of AF1773-1, B1240-14 and B1429A-6.

White-skinned Cornell Clones: Allegany, Norwis, NY103 and NY109 produced the best marketable yields (Tables 8 & 9). Norwis, NY103, and Q3-12 tubers were the largest in the experiment. Entries that had specific gravity readings greater than 1.080 were: Allegany, P32-3, P63-1, P73-2, Q3-12

and Q8-2. NY103 and NY115 had the best tuber appearance. Other lines with attractive tuber type were NY109, NY110, P32-3 and Q3-12.

Red-skinned Clones: Chieftain, Redsen and Red Ruby produced similar marketable yields (Tables 10 & 11). Redsen had the most intense red color and the best appearance. Tubers of B0811-4 are very small, have a pink smooth skin and yellow flesh. This line could fit a niche market even though its yield is very low. Other lines that may fit niche markets are B0811-13 (red netted skin with yellow flesh), R174-1 (purple skin and mottled purple flesh) and R174-2 (smooth red skin with pink mottled flesh).

Russet-skinned Clones: The yield of tubers greater than eight ounces was poor for all entries (Tables 12 & 13). The performance of Century Russet was disappointing. The best yielding russet was B9922-11. This line has golden nematode resistance. Tubers are oblong to long, heavily netted and have a high specific gravity. Although not a major problem in this experiment, hollow heart has been a concern in a cultural practice experiment this year and other experiments in the past.

Observation Trial: Data from a non-replication trial on yield, appearance, specific gravity and internal defects of early selection clones and recently released varieties are presented in (Table 14).

Clone X N Rate X Spacing: NY103. The highest total and marketable yields were produced at the six inch spacing and sidedress rate of 100 lbs N/A (Tables 15 & 16). However, the only significant effect was that of spacing on total yield. Size distribution and specific gravity were not affected by treatment.

NY109. Total and marketable yields were highest at the 100 lbs N/A sidedress rate and six inch spacing but the yields at 0 and 50 lbs N/A sidedress rates were nearly identical (Tables 17 & 18). The nine inch spacing resulted in a higher percentage of tubers greater than 2.5 inches than the six inch spacing. Specific gravity was not affected by treatment.

B9922-11. Total and marketable yields increased when sidedress nitrogen was applied but the 50 and 100 lbs N/A rates produced similar yields (Tables 19 & 20). Yields were not affected by spacing. There was no hollow heart at the six inch spacing and no sidedress. The amount of hollow heart was greatest at the nine inch spacing.

<u>Storage Results:</u> After-cooking darkening and blackspot ratings for clones grown in 1996 are given in (Table 21).

Acknowledgments: Seed was provided by R.L. Plaisted, Cornell University; K.G. Haynes, USDA; G.A. Porter, University of Maine; Childstock Farm, Malone, N.Y. The assistance of Bennett Orlowski, Rod Zeltmann, Mark Sisson, Sandra Mulvaney and Carole Brush is greatly appreciated.

autoclave for 7 minutes and rated after 20 minutes. Blackspot (BS) determinations are based on approximately ten tubers per replication. Tubers impact. Each tuber received a blow in each of two locations about 1 to 2 cm from the stem end. The bruising was done by dropping a 175 gram were stored at 40° F and bruised between 1/27/97 and 2/4/97 and then stored at 55° F. Bruised areas were peeled and evaluated two days after After-cooking darkening (ACD) rating based on a scale of 1 to 5; 1 = severe darkening, 5 = no after-cooking darkening. Five tubers rated per weight a distance of 30 cm. The point of impact was marked by inking the base of the weight. Ratings are based on a scale of 1 to 6 with 1 = replication, four replications in each experiment. Tubers were peeled and dipped in a 0.5% solution of sodium bisulfite and cooked in an severe discoloration and 6 = no discoloration. New York - Upstate D.E. Halseth, W.L. Hymes R.W. Porter, R.L. MacLaury

Program Scope:

Potato variety yield trials were conducted in four counties in upstate New York in 1997 in which a total of 27 named and 98 numbered clones were evaluated. Eight replicated yield trials were conducted at the Thompson Vegetable Research Farm at Freeville in Tompkins County on a Howard gravelly loam soil. Grower trials were conducted on mineral soils near Arkport (Steuben County) and Gainesville (Wyoming County) and on muck soil near Savannah (Wayne County). Trials at Freeville and Gainesville were irrigated, and all trials were grown using standard commercial cultural practices. As evaluation of potato lines with golden nematode (GN) resistance is of high priority, 8 named and 43 numbered entries in these trials have GN resistance. Marketable yield, tuber quality and appearance, maturity, storage life and chip processing potential are among the important characteristics which are evaluated.

Research Farm Results:

In the early maturity trial Andover yielded as well as the GN susceptible Superior, our industry standard for earliness. Andover also had fewer internal defects and much better tuber appearance ratings. AF1470-6 had the highest yield and lowest specific gravity. The medium maturity trial with 12 entries had 9 GN resistant clones and varieties with marketable yield above 300 cwt. per acre. Advanced Cornell clones NY102, NY109, and NY115 had marketable

yield above 350 cwt. per acre while B0564-9 and NY119 (P63-1) exceeded 400 cwt. per acre. NY115 had the fewest internal and external defects and the best tuber appearance. Itasca had the highest yield while MaineChip again the highest specific gravity. Of 15 entries in the medium-late trial, all 6 GN lines had marketable yields above 300 cwt. per acre, and NY101 topped out at 475 cwt. per acre. University of Maine-developed Quaggy Joe and AF1773-1 had the highest total yields and the lowest specific gravity. Atlantic and Snowden had the highest specific gravity, NY101 and Snowden the highest tuber set, and NY103 the best tuber appearance. The late maturity trial had 8 GN lines with marketable yield above 300 cwt. per acre, with NY112 reaching 456 cwt. per acre. Atlantic had the highest specific gravity, Lili the most external and internal defects and Allegany the best tuber appearance. In the advanced Cornell clone trial there were 12 new entries with excellent yield potential, ranging from 350 to 515 cwt. per acre marketable yield. All were lower than Atlantic in specific gravity and percentage of defects (except for R41-18) and higher in marketable yield. There are few GN resistant red-skinned clones currently available. NY118 (P49-19R) from the Cornell program and B0811-13 from the USDA were the only GN resistant red-skinned lines tested at Freeville in 1997. Both had very good marketable yields, as good as Chieftain (GN susceptible), which currently is the highest yielding red in the potato industry. NY118 has very attractive, uniform tubers, a very low percentage of defects, and a medium-red color similar to Chieftain. NorDonna had a dark red skin color similar to Redsen, but its marketable yield was 47 cwt. per acre higher. Only one GN russet-skinned clone was available for our russet yield trial. This clone, B9922-11, in the past has frequently

out-yielded the industry standard Russet Burbank in marketable yield, but this season was about equal in yield. It had the highest specific gravity and was ranked as the best in tuber appearance for the russets. Century Russet and Russet Norkotah continue to have higher marketable yields than Russet Burbank. There were 10 advanced "B" clones in the USDA trial compared to Atlantic and Monona. Seven clones had higher marketable yield than Atlantic, and one, B1240-14, had specific gravity reading of two units above Atlantic. B1240-14 and B1408-3 had significant hollow heart problems while B0856-4 and B1240-12 had the best tuber appearance ratings.

Grower County Trial Results:

Round red and white tablestock selections were grown in the muck soil grower trial in Wayne County. Yields were extremely high, with round white clones NY101, NY112 and Reba producing marketable yields above 400 cwt. per acre. Atlantic had the highest specific gravity, and NY109 the lowest. Again NY101 had the highest average tuber number (11.7 per foot of row) and Q3-12 the highest tuber weight (7.1 ounces). The red-skinned trial had a much broader range in marketable yield, from 172 cwt. to 512 cwt. per acre. While Chieftain typically had the highest total and marketable yields, clone NY118 was a close second in both catgories. Redsen (GN susceptible) still produces the brightest red color which is demanded by the tablestock trade. The Steuben and Wyoming County chip processing trials were on mineral soils and had 11 GN clones (3 varieties and 8 breeding lines) yielding above 300 cwt. per acre marketable yield at both sites. The yellow-fleshed tablestock clone NY101 was included in these trials for dicing studies and had the highest yield at both sites, producing 534 cwt. per acre in the Wyoming County trial. B0178-34, Pike and Snowden had the highest specific gravity reaching 1.090 or higher at both trial sites. Snowden had hollow heart problems at both processing trial locations while NorValley (ND2417-6) had knobs and internal defects.

Table Heading Explanations:

Marketable yield in cwt/a was calculated from total yield less: external defects; undersize tubers (smaller than 1 7/8 inches); and oversize tubers (over 4 inch diameter).

Percent marketable yield represents the percentage that each entry's marketable yield is of that of a specified standard variety in that trial.

Size distribution percentage is the weight of a specific size category divided by total yield (including defects).

Specific gravity was taken by potato hydrometer.

Vine maturity ratings were on a nine point scale:

- 1 = all plants completely dead (very early maturity)
- 9 = all plants full green (very late maturity)

Tuber shape was classified using the code:

- 1 = round
- 2 = mostly round
- 3 =round to oblong
- 4 = mostly oblong
- 5 = oblong
- 6 = oblong to long
- 7 = mostly long

8 = long

9 = cylindrical

Tuber appearance was subjectively evaluated using the scale:

1 = extremely rough or otherwise unattractive9 = very uniform and attractive

External defects were rated on all material graded. Internal defects were made on a subset of tubers, usually 10 per replication, taken from size categories 3 and 4.

Acknowledgements:

Cooperative Extension Agents Carl Albers, Steve Childs, and Carol MacNeil coordinated grower trials.

Special thanks is given to grower-cooperators: Murray Mahany and family, Bob Martens and Jim McCormick.

Seed of new clones was provided by: Robert Plaisted, Cornell University; Alvin Reeves, University of Maine; Kathleen Haynes, USDA; and Gregory Porter, NE184 Project. Donation of seed by Gary Pryputniewicz and Kent Farms, Inc. is greatly appreciated.

The Freeville crew is acknowledged for their excellent cooperation in maintaining the research farm plots.

Industry Cooperators

Hettema Seed Potatoes, Fredericton, N.B. Canada Frito Lays Inc., Rhinelander, WI Wise Foods Inc., Berwick, PA

Methods

Eastern tests were planted in March and harvested in June and July with growing days between 106 and 110 days depending on location and crop status. The western trial was planted in May and harvested in August with 113 growing days. All entries were planted in a randomized complete block design with 4 replications (i.e. 4 plots per entry), excepting the unreplicated, preliminary evaluation trial, which had only one plot per clone. Each plot consisted of 1 row with 28 hills spaced 9 inches apart. Spacing between rows was 38-inches at all sites, except UMRS which was 45 inches. Fertilizer, weed and pest control practices were in accordance with those practiced by the cooperators. Plots were dug using a single row digger and hand harvested. Grower trials were graded using a portable Lockwood Grader which sorts 2 grades; 1's = >1 7/8" and 2's = >7/8" to 1 7/8" which are roughly equivalent to USDA sizes A and B grouped together, and USDA size C, respectively. At the TRS/VGJREC, potatoes were graded to three classes: $1's = \ge 17/8$ ", 2's = 11/2" to 1 7/8 " and 3's = \leq 1 1/2" roughly equivalent to USDA A's, B's and C's, respectively. Culls were weighed separately in all trials. After grading and weighing plots, 40 marketable tubers (10 tubers/replication) were sampled randomly from each entry. The tubers were cut and scored for the presence or absence of hollow heart, heat necrosis and any other internal defects. Subsamples of marketable tubers were also taken from each plot and bulked by entry for specific gravity readings and chipping tests. Specific gravity was determined using the weight-in-air/weight-in-water method, and chip colors were provided by Wise Foods, Berwick, PA.

Results

The season began with warmer, drier weather than normal for most potato production areas in eastern NC. The favorable warm February-March conditions were counterbalanced, however, by abnormally cool and dry growing conditions during April to May.

A total of 143 clones were evaluated this year. The data for each trial are summarized in Tables 1-8. Each table has two parts, the first being devoted to yield and specific gravity information (a), and the second relating potato plant and tuber quality parameters and chip color score (b). For each clone evaluated, tuber quality and appearance comments were made during harvest and grading, and while specific gravity measurements were being made. These notes are contained in the second table and a

^{1.} Assistant Professor and Research Technician, respectively. Department of Horticultural Science, Vernon G. James Research and Extension Center, North Carolina State University, 207 Research Station Road, Plymouth, NC 27962

description of the rating scales is given in Appendix 1. It should be noted that the Carlita and Adora entries arrived late and were planted later than the other entries in the McCotter Farm trial (7 days late) and the Bright Farm trial (2 days late).

Comments on some of the more promising clones, which have been evaluated for more than two years in at least three locations in NC, are provided below. Please note, however, that many other clones may have performed well in 1998 (see individual tables). If they are not specifically mentioned below, it most likely indicates that, as of yet, there is not sufficient information to comment on them.

Comments on promising, newly released varieties and advanced clones grown in NC's environment

Andover was recently released from the Cornell University, New York breeding program where it was tested as NY E55-44. It is an early to medium maturity, slightly netted, buff-skinned, very round variety. It produces uniform, medium-sized potatoes that are very nice in appearance with good skin and few defects. Over four trials in 1996 its average marketable yield was 150% of Atlantic, while in five trials in 1995 its marketable yield was 85% of Atlantic. In 1997, its marketable yield was 63% of Atlantic, and over all trials (11) its marketable yield has been 116% of 'Superior'. It chipped very well at all sites with chip scores of 2-3. Its gravity is only slightly lower than that of Atlantic. Heat necrosis and hollow heart are not problems. It is resistant to golden nematode and common scab. Andover is a very promising chipping variety, but adverse (drought and severe heat stress) growing conditions may significantly impact its yield in some years. This tendency has also been noted in NJ, NY, PA and VA. We plan to evaluate this clone next year at three sites, and would be interested in having a few growers try it out on a limited basis in 1998-1999.

Quaggy Joe was recently released by the University of Maine breeding program. It was evaluated in NC as AF1470-17. Quaggy Joe is a medium maturing, white-skinned, round, tablestock selection with shallow, pink eyes and white flesh. It does not chip. It produces medium to large-sized potatoes that are nice in appearance. Its average marketable yield in NC over three years was 108% of Atlantic. It is resistant to net necrosis, blackspot and shatter bruising, and shows a moderate reaction to early blight, *Verticillium* wilt, and *Fusarium* tuber rot. It is susceptible to scab and hollow heart, and is

metribuzin sensitive. Unless requested, we will not be evaluating this variety in 1998.

Reba was recently released from the Cornell University, New York breeding program where it was tested as NY 87. Reba is a medium to late season, round, white, smooth-skinned chipstock and tablestock potato. Over seven trials from 1995-1997 at four sites its average marketable yield was 83% of Atlantic. It chipped very well at all sites with scores of 3-4, and its gravity is slightly lower than Atlantic. We have seen heat necrosis in this clone at one site in NC in one year (1997), but we have not seen any hollow heart. It is resistant to the golden nematode. We will be testing this clone again in 1998.

Salem was recently released from the Cornell University, New York breeding program where it was tested as NY 84. Salem is a medium to late season, mostly round, white, slightly netted tablestock potato with white flesh. Over nine trials from 1995-1997 at four sites, its average marketable yield was 103% of Atlantic. In 1997, we chipped it at one trial and it yielded a score of 4, so it might chip directly from the field in NC. Its gravity is only slightly lower than Atlantic. Hollow heart or heat necrosis do not seem to be a problem with this clone in NC. It is resistant to the golden nematode and has very good scab resistance. We will be testing this clone again in 1998.

AF1424-7 is a medium maturing, bright, white-skinned, round selection with shallow eyes. We've tested it in NC over three years at three sites (9 trials) and it has yielded 83% of Atlantic. It chipped well at all sites with scores of 3-4. Its gravity is only slightly lower than that of Atlantic. At one site this clone had some rhizoctonia and a few growth cracks. At the research station in 1996 we noted the presence of pitted scab, but this was not noted in 1997. We plan to evaluate this clone in 1998 at three sites.

AF1433-4 is a medium maturing, white-skinned, round selection. It produces a uniform, medium-sized potato that is nice in appearance with good skin. This clone has been tested in NC over three years at three sites in 11 trials and it has yielded 85% of Atlantic. It chipped well at all sites with scores of 2-4. Its gravity is lower than that of Atlantic. In 1997, it showed weak internal necrosis symptoms. We plan to evaluate this clone in 1998 at three sites.

AF875-15 is a medium maturing, smooth, white-skinned, round selection. In eleven trials in NC over

the last three years its average marketable yield was 107% of Atlantic. Its gravity is slightly less than Atlantic. It does get very slight heat necrosis, but probably not enough to interfere with the quality of chips. Hollow heart is not a problem. Growth cracks have been the major defects in some years in NJ, PA and ME, and we have seen some in NC, too. It is resistant to *Verticillium* and net necrosis. Chip color is about the same as Atlantic. It will be tested at two sites in 1998.

B0178-34 is an medium to late maturity, slightly netted, buff-skinned, round to oblong variety. It produces medium to large-sized potatoes that are nice in appearance with good skin and few defects. Over five trials in 1995-1997, its average marketable yield was 99% of Atlantic. It chipped very well at all sites with chip scores of 3. Its gravity is equal or greater than that of Atlantic. Heat necrosis and hollow heart are not problems. It is resistant to golden nematode, net necrosis and PVX, but susceptible to scab. It has a short dormancy period. We plan to evaluate this clone next year at three sites, and would be interested in having a few growers try it out on a limited basis in 1998-1999.

B0564-8 is a medium maturing, round, white-skinned selection. We've tested it in NC over three years in 10 trials and it has yielded 117% of Atlantic. It produces a nice crop of potatoes with good size distribution for chipping. It chipped well at all sites with scores of 3-4 and its gravity is comparable to that of Atlantic. At one site this clone had some *Rhizoctonia* and a few growth cracks. At the research station in 1996 we noted the presence of deep-pitted scab, but we didn't find scab in this clone at all in 1997. We plan to evaluate this clone next year at four sites.

B0564-9 is a medium maturing, round, whiteskinned selection. We've tested it in NC over three years in 8 trials and it has yielded 130% of Atlantic. In three trials in 1996 its average marketable yield was 147% of Atlantic. In two trials in 1997, its average marketable yield was 107% of Atlantic. Its gravity is only slightly lower than that of Atlantic. Its chip scores (generally 4's and 5's) are not as good as those of B0564-8, but B0564-9 produces larger tubers with a nicer appearance, and a nice size distribution. This clone possesses moderate levels of resistance to Verticillium wilt, but is susceptible to common scab. Heat necrosis and hollow heart do not appear to be problems in either B0564-8 or B0564-9. We plan to evaluate this clone next year at three sites, and would be interested in having a few growers try it out on a limited basis in 1998-1999.

NY103 is a medium maturing, round, smooth, bright white-skinned, chipstock and tablestock selection. We've tested it in NC over three years at four sites (5 trials) and it has yielded 91% of Atlantic. It chipped very well at all sites with scores of 2-4. Its gravity is ca. .008 lower than that of Atlantic. Heat necrosis and hollow heart do not appear to be problems. We have seen some soft rot in this clone in our higher organic soil trials, but we are not sure if this will be a serious problem. We plan on evaluating this clone in again 1998 in at least two trials.

Acknowledgements

Without the assistance of the growers, county extension agents and NCDA Tidewater Research Station and Upper Mountain Research Station staff, this work could not be conducted. We are grateful for their continued support and assistance. Wise Foods, Berwick, PA is also gratefully acknowledged for conducting chip tests, and for helping to harvest and grade trials. Frito Lays, Inc. and Hettema Seed Potatoes provided unrestricted gifts which benefited the project. This project is partially funded by The North Carolina Potato Growers Association. Their continued support is much appreciated.

NORTH DAKOTA POTATO VARIETY TRIALS AND BREEDING REPORT Richard Novy¹, Bryce Farnsworth¹, and Mike Schwalbe¹ in collaboration with Nikolay Balbyshev¹, Neil Gudmestad², Edna Holm³, Jim Lorenzen¹, Roald Lund¹, Paul Orr⁴, Duane Preston⁵, Gary Secor², Joe Sowokinos⁶, Brad Brummond⁷.

Crossing and Seedling Production

In 1997, a total of 2,601 crosses were made in the greenhouse resulting in the production of 424 Thirty percent of the families had one or families. more parents that were identified as having late blight resistance. During the summer of 1997, 123,414 seedlings were grown for minituber production--a 33% increase since 1996. The increase in seedling numbers reflects the breeding program's efforts to develop late blight resistant cultivars. Twenty-two percent of the potato families planted for seedling tuber production in 1997 had one or more parents that were identified as having late blight resistance. In collaboration with Drs. Gudmestad and Secor, approximately 7,000 potato seedlings were screened for late blight resistance using a detached leaf assay this past summer. These evaluations provide the breeeding program with valuable data on late blight resistance within a family at a very early stage of the breeding program.

1st Year Selections

Approximately 84,500 red and white-skinned seedlings were grown at the Langdon Agricultural

Department of Plant Sciences;
 Department of Plant Pathology;
 Department of Food and Nutrition, all at North Dakota State University;
 USDA/ARS;
 Ext. Service, NDSU/UMN;
 UMN;
 Walsh Co. Ext. Service, NDSU.

Technical assistance of the following people is gratefully acknowledged:

Dean Peterson, Myron Thoreson, Galen
Thompson, Anne Erickson, and Louise Heinz.
Special thanks to Carl Hoverson and Brian
Vculek for the use of their land and the maintenance of the irrigated trials during the 1997 growing season.

Financial support of the breeding program by the Red River Valley Potato Growers Association is gratefully acknowledged. Experiment Station, and an additional 8,200 russet seedlings were grown and evaluated at the Horticulture Research Farm at Absaraka. The russet selections were moved to Absaraka (with its associated warmer soil temperature) to improve the expression of russeting on the tubers. However, the presence of the russet seedlings at Absaraka has utilized land that could be used for the evaluation of a greater number of second year selections. Rather than be limited at this critical stage of the breeding program, the decision was made to move the russet seedlings back up to Langdon in 1998. Seedlings were planted on June 6th at Absaraka and on May 20th and 21st at Langdon. Evaluation and harvesting was conducted September 8-10 at Langdon and October 26th at Absaraka.

Advanced Selections

Replicated plantings of 1,072 second year selections from the 1996 seedling crop were planted at Grand Forks and Absaraka. A total of two hundred and twenty-two second-year selections were saved at harvest from both sites. Of the advanced material (>2 year material), 389 selections were planted and 162 were saved at harvest. Third year and older selections were planted at the Casselton Agronomy Seed Farm for clean seed stock production.

Cultivar and Advanced Selection Yield Trials Trials were conducted under dryland conditions at Grand Forks (Potato Research Farm) and at Park River, ND. In addition, two irrigated trials were established on growers' fields near Oakes and McCanna, ND. Spacing, fertility, planting and harvest dates are listed in Table 1. The four trials, with a few entry differences, were replicates of one another. They consisted of standard and newly released varieties, and advanced NDSU, Idaho and Oregon selections. The replication across sites allowed for the assessment of the potato selections and cultivars under both dryland and irrigated conditions. The Grand Forks site also consisted of two additional trials -- a Secondary trial consisting of additional ND selections, and an Out-Of-State trial consisting primarily of entries from Texas and Europe.

Plots in the dryland and irrigated trials consisted of four replications of 25 and 20 hills respectively. A randomized complete block design was used at McCanna, Park River and Grand Forks, while a completely randomized design was used at Oakes.

Irrigated Sites

McCanna: The average total yield of the 35 entries at the McCanna site was 450 cwt/A. Average U.S. No. 1 yield was 396 cwt/A. Lili, a potential cultivar for fry production with yellow flesh and skin was the the highest yielding with a U.S. No. 1 yield (cwt/Acre) of 566 (Table 2). ND860-2 was the lowest yielding entry at 247. ND5084-3R was the highest-yielding red at 502, outyielding Red Pontiac at 479. The size distribution between ND5084-3R and Red Pontiac was quite different however, with Red Pontiac having a much larger percentage of tubers in the >3" category (42% -vs- 12%). ND2470-27 was the highest yielding white-skinned chipping variety at 513, significantly outyielding the standard chipping cultivars Snowden (370), and Norchip (350). ND2470-27 also had no incidence of internal defects among 48 tubers examined. Again, for the second year, the highest yielding russet in the McCanna trial was the Idaho selection A79180-10 at 487, which significantly outyielded Russet Burbank at 326. A79180-10 was rated quite highly for french fry production in 1995, but received lower but acceptable ratings in 1996 (Table 9).

Oakes: The average total yield of the 34 entries evaluated at this site was 317 cwt/A. Average U.S. No. 1 yield was 248 cwt/A. The Idaho russet selection, A79180-10, was the highest yielding entry for U.S. No. 1's at 381, significantly outyielding the standard fry cultivars Russet Burbank (200) and Shepody (229) (Table 3). ND860-2, as at McCanna, was the lowest yielding entry at 208. ND2470-27, a white-skinned chipping cultivar was tied with Red Pontiac for the second-highest vielding entry at 346. As noted in the McCanna trial, ND2470-27 had a low incidence of internal defects at Oakes. ND5084-3R, the highest yielding red in the McCanna trial was the second-highest yielding red after Red Pontiac at 320. ND3574-5R was also worthy of mention, closely following ND5084-3R at 303. Both ND5084-3R and ND3574-5R had a lower incidence of hollow heart than Red Pontiac.

Non-Irrigated Sites

Park River: Last used as a test site in 1994, a trial was again established at Park River in collaboration with Brad Brummond, Walsh County Extension Agent. Average total yield of all entries at the site was 233 cwt/A. Average U.S. No. 1 yield at the site was 164 cwt/A. The highest yielding entry was Red Pontiac at 281 followed closely by NorValley at

278 (**Table 4**). Both *NorValley* and *Red Pontiac* significantly outyielded all other entries in the trial. Again, A79180-10 was the highest yielding russet entry at 215.

Grand Forks: Three trials were conducted under dryland conditions at the Potato Research Farm. These trials (State, Secondary, and Out-of-state) looked good up to the end of June into early July when approximately 4.5" of rain fell during an 11 day period. Flooding of the trials occurred with the impact being extremely low yields. The data from the trials has been summarized for this report (Tables 5, 6, and 7), but the relative merit of the entries in these trials cannot be effectively assessed due to the impact the flooding had on yields. Nonetheless, this yield data does provide an assessment of performance in water-saturated soil. Worthy of mention was ND5822C-7 (Table 6), with a high (89%) U.S. No. 1 percentage resulting in a U.S. No. 1 yield of 143 cwt/A.

Summary: The performance of the entries at the Oakes, McCanna, and Park River sites have been summarized in Table 8. The Grand Forks trial has not been included due to the poor yields obtained.

Processing Trials

French Fries: Samples were tested for french fry quality by the Food and Nutrition Department using a taste panel. Sensory characteristics evaluated were fry color, flavor and texture (Table 9). All clones evaluated had acceptable scores with the exception of clone ATX84378-1Ru which rated poorly for both color and texture.

Baking, Boiling and Microwaving: Tubers of 25 potato clones that had been grown at both Grand Forks (dryland) and McCanna (irrigated) in 1996 were evaluated for the following sensory characteristics in each of three cooking categories:

<u>Boiling</u>: Characteristics examined were color immediately and four hours after cooking, mealiness, and flavor.

<u>Baking</u>: Mealiness, color, and flavor were evaluated.

<u>Microwaving</u>: Mealiness, color, and flavor were evaluated.

The summation of scores across all three cooking categories at both sites identified the following top 10 cultivars and advanced selections: *Shepody*,

ND2470-27, ND4027-4Russ, A79180-10, ND2471-8, *Atlantic*, *Russet Burbank*, I426, ND2676-10, and N8-14.

Among eight European cultivars grown at the Carrington site in 1996, *Asterix* and *Disco* received the highest ratings.

Chipping: The flooding at Grand Forks last year adversely affected chipping quality, with no selections or cultivars chipping acceptably from 43°F storage (with or without reconditioning).

<u>Promising Selections and Cultivars--Summary for</u> 1997

White Chippers

NorValley, a white chipping cultivar with coldchipping properties and a low incidence of internal defects, significantly out-yielded all other white selections/cultivars under dryland conditions at the Park River site. In the irrigated trials, its average U.S. No. 1 yield was 314 cwt/A--very similar to Snowden at 318 cwt/A and less than that of Atlantic at 388 cwt/A.

ND2676-10 also has cold chipping properties and was entered in the North Central Regional Potato Variety Trial (NCRPVT) for the second year in 1997. In the 1996 NCRPVT, (6 trial sites) its average U.S. No. 1 yield was 248 cwt/A compared to *Snowden* at 282 cwt/A, *Norchip* at 234 cwt/A, and *Atlantic* at 317 cwt/A. Its average U.S. No. 1 yield under irrigated conditions was 368 cwt/A. At Park River it yielded 152 cwt/A. In the past it had been noted for erratic yields that were thought to be due to poor quality seed. Higher quality seed has since been used with an associated better performance.

One of the highest yielding chippers in the irrigated trials in 1996, ND2470-27 again was outstanding in 1997. It was the highest-yielding white chipper at both Oakes and McCanna. Average U.S. No. 1 yield across the two irrigated sites in 1997 was 430 cwt/A. At Park River it also was among the top three yielding white chippers at 190 cwt/A. It also has cold chipping properties and could be used as tablestock with high sensory ratings for boiling, baking, and microwaving in 1995 - 1997.

Other white chippers that performed well in 1997 were ND4778-2 and N8-14. ND3828-15 was entered in the NCRPVT in 1997--a decision as to

carry it forward another year will be made based on its performance in the NCRPVT.

Red Selections

Among the red selections, ND3574-5R and ND5084-3R were the top yielders in 1997. Both have a deeper red color than *Red Norland* from the field. U.S. No. 1 yields of ND5084-3R, ND3574-5R, and *Red Pontiac* averaged across Oakes, McCanna, and Park River were 343, 300, and 368 cwt/A, respectively. ND5084-3R and ND3574-5R tend to have a smaller percentage of oversize tubers than does *Red Pontiac*. A potential weakness of ND3574-5R is a short tuber dormancy. This may be negated by the use of sprout inhibitors. ND5084-3R has been noted as having a problem with stolon attachment. Increasing the time between vine kill and harvest may allow the stolons to separate more cleanly from the tubers.

With a yield and maturity similar to *Red Norland*, ND3196-1R has very nice tuber type and a darker skin color than *Red Norland*. For the first time this year, growth cracks were observed very early in the development of tubers at the Park River site. *Red Norland* also showed this same problem at the site, and cullage was high in both ND3196-1R and *Red Norland*. This problem was not observed at the other sites, or in other trials in the past. Growers in the immediate area also commented on an increased incidence of growth cracks in the red cultivars. The environmental conditions responsible for the increased incidence of tuber cracking are not known.

ND2225-1R has entered its third year year in the NCRPVT. Based on the results of this year's trials, a decision will be made regarding its release as a cultivar. Its main weakness is the development of russeted skin or "buckskin" under certain field conditions (thought to be heavier soils). This year, it was noted that a high percentage of seed pieces developed what appeared to be soft rot soon after cutting. This had a negative impact on stand establishment and subsequent yields in the 1997 trials.

Russets

The most promising russet selection in 1997 was A79180-10. This Idaho selection was the highest yielding russet at McCanna in 1996 and at McCanna, Oakes, and Park River in 1997. Its U.S. No. 1 yield across all three sites in 1997 was 361 cwt/A as compared to *Shepody* at 292 cwt/A, and *Russet Burbank* at 217 cwt/A. In 1995 it had

excellent french fry evaluation score--somewhat lower but acceptable in 1996. It also has scored well for sensory qualities and could be a dual-purpose selection. However, its lightly-russeted skin, may limit its use for tablestock.

Other promising russet selections are ND4093-4Russ and ND4027-4Russ. While not as high yielding as A79180-10, these russet selections compare favorably with *Russet Burbank*. ND4093-4Russ has a nice tuber type with excellent russeting. In sensory evaluations it compared favorably with *Russet Burbank* for fry color, taste, and texture. However, its lower specific gravity may limit its use for processing. ND4027-4Russ, with favorable sensory ratings for boiling, baking, and microwaving, has a higher specific gravity than ND4093-4Russ and could be used as a dual-purpose russet.

Germplasm Enhancement Update

A major objective of the NDSU program is the incorporation of resistance to the newer genotypes of *Phytophthora infestans*, such as the US-8 genotype that predominates in North Dakota. Crosses utilizing parents with genetic resistance continued this past winter and their progeny were grown in the greenhouse this past summer. Field selections were also made within late blight resistant families this Fall. These clonal selections will be grown in the greenhouse this winter and evaluated for late blight resistance in collaboration with Drs. Gary Secor and Neil Gudmestad of the Plant Pathology Department at NDSU.

Early in 1996, the breeding program requested and received late blight resistant germplasm from the USDA potato breeding programs at Beltsville, MD and Aberdeen, ID. The material was received as both sexual seed and as single minitubers. These clones (when extra seed became available) as well as selected potato cultivars were included in the late blight plots at Prosper, ND in 1997. In the Fall, hills of the resistant clones were dug and evaluated and those with the best agronomic properties selected. Table 10 provides information on the foliar resistance of the cultivars and the selected blight-resistant clones. The cultivars displayed a range of resistance, with some showing susceptibility while others showed moderate resistance. Tubers of the selected experimental clones are also currently being tested for resistance to tuber blight. The selected clones and those

cultivars with moderate resistance to foliar blight will be incorporated into our crossing block this coming winter.

The breeding program is also incorporating genetic resistance to *Verticillium* wilt, early blight, silver scurf, PLRV, PVY, green peach aphid and Colorado potato beetle into commercially-acceptable clones. ND5822C-7 is an example of our efforts in this area. Identified as resistant to Colorado potato beetle in preliminary screenings by Drs. Lorenzen and Balbyshev, ND5822C-7 is also notable for its yield and tuber-type under the stressful growing conditions at the Grand Forks site in 1997 (**Table 6**).

Table 1. Spacing, Fertilizer, Soil Type, Planting and Harvest Dates of the 1997 North Dakota Potato Variety Trials.

	Spa	Spacing	1			
Location	Row	Plant	Fertilizer Applied	Soil Types	Planting Date	Harvest
Park River	38"	12"	40-10-10 @ 250 lbs/A	Glyndon silt loam	5-10	9-4

^{*}All scores are based on 3 and 6 separate evaluations of each cultivar for Grand Forks and Carrington, respectively. Six panelists participated in each evaluation for a total of 18 and 36 individual evaluations. The only exception was the Grand Forks' *Russet Burbank* control/reference sample for which there were 300 individual evaluations.

^{*}Plants infected with US8 (A2) were transplanted into plots to act as inoculum source in mid-July. No fungicides were applied during the growing season. Due to space limitations and a limited amount of experimental clonal seed, plots were unreplicated and consisted of between 2-10 hills / clone.

OHIO

Richard Hassell, David M. Kelly, E.C. Wittmeyer, John Elliott

Introduction to NE184 Trial

Twenty-eight varieties and clones from the NE184 Regional project were evaluated in replicated field trials located at the Ohio Agricultural Research and Development Center, Wooster, Ohio.

Methods

The seed samples when received from the NE184 project nursery were stored under recommended temperature and humidity conditions. A randomized complete block design with four replications was used.

The soil type is a well-drained Wooster silt loam with a pH 6.7, a phosphorus level of 112 lbs/A and a potassium level of 206 lbs/A, according to the analytical procedures of the Research and Extension Analytical Laboratory at the Ohio Agricultural Research and Development Center.

Fertilization consisted of 600 lbs/A of 10-20-20 disked in prior to planting and 600 lbs/A 10-20-20 banded at planting.

Following harvest on September 18, samples for chip quality evaluation were taken to the Pilot Plant, The Ohio State University, Columbus, Ohio, where the samples were held at ambient temperatures until early October (approximately 20 days) when chipping and specific gravity determinations were made. In addition, other samples were graded for market quality. At the time 10 tubers were taken at random from each replicate and checked for hollow heart and internal necrosis ratings (see Table 2).

Weather Conditions

Rainfall during the growing season (May-September) was 14.76 inches, 3 inches below the long-term average for Wooster.

Results:

This trial yielded several cultivars and selections that showed promise and may be included in the 1998 trial: NorDonna, BO 766-3, NY 103, Snowden, Cherry Red, and AF 1565-12.

Specific comments follow below.

Atlantic: Round to oval tubers--irregular surface--poor appearance. Round to slightly oval, heavy netting, tendency for tubers to be flattish. Wide range in size. Heavy yielder.

NorDonna: Round to slight oval shaped tubers with medium red color. Trace of second growth. Tubers are small to medium size. Appears to have better surface texture (marketability) than B0811-13. Promising-try again.

B0766-3: Round to slightly oval tuber with buff appearance. Some tubers have irregular surface, trace of second growth, trace of misshapened tubers. Appears to have sizing ability. Try again. Promising.

B0564-8: Round to slightly oblong tubers with cream colored appearance. Many small tubers. Large tubers have an irregular surface. No future.

Yukon Gold: Round tubers with cream colored skin. Wide range in size. Eyes redpink. Irregular surface on larger tubers. No future.

Quaggy Joe: Round to oval tubers with light buff appearance, smooth surface. Excessive greening. Too much irregular surface. Too many tubers have an irregular surface. No future.

Katahdin: Round to slightly oval tubers with buff appearance. Most large tubers have irregular surface. Many misshapened tubers. Wide range in size. Doubtful future.

Kennebec: Round to oval tubers with light buff appearance. Severe irregular surface. Many tubers are misshapened. Second growth is serious. No future.

BO811-13: Round to oval tubers, dark red surface. Tubers tend to have irregular surface. Small to medium size. Biggest problemrough appearance of surface. Doubtful.

B9922-11: Round to oval to oblong russet-type tubers with medium to heavy netting. No second growth. Major problems; irregular surface and misshapened. No future.

NY103: Round tubers with light tan-buff appearance, some tubers have irregular surface. Fairly uniform size. Trace of surface scab. Poor yield. Try again.

NY102: Round tubers with buff appearance and light netting. Apical end (on some tubers) tend to be recessed. Tuber size tends to be small. Larger tubers tend to have irregular surface.

Snowden: Round tubers with heavy netting. Apical end tends to be deep. Stem end is deeply recessed. Tubers have pink tinge.

Larger tubers have irregular surface. May have yield ability. No future fresh market (appearance)--may be ok for processing.

Cherry Red: Round to oval shaped tubers with light to medium red appearance. Surface tends to have netted skin. Smooth surface. Try again.

NY87 (**Reba**): Round tuber with buff appearance, light netting, larger tubers tend to have irregular surface. Trace of second growth and trace of greening. No future.

AF1480-5: Round to oval shaped tubers with light buff appearance. Second growth and misshapened are problems. No future.

AF1437-1: Round tubers with buff appearance, some netting. Shallow eyes. Apical end and stolon end tends to be indented. Too much variability in size/shape. No future.

ND2417-6 (NorValley): Round to oval shaped tubers with buff appearance. Major problem is irregular surface. Small size. No future.

AF1565-12: Round tubers with light-almost white surface. Medium size tubers are quite uniform. Some tubers tend to have irregular surface. Promising--fresh market.

AF1615-1: Round to slightly oval tubers with buff appearance. Some tubers have irregular surface. Second growth could be problem. May have yielding ability, but small tuber size. No future.

Dk Red Norland: Round to slightly oval tubers with light red appearance. Larger tubers tend to have an irregular surface. Color is too light for present market.

ND2471-8: Round to oval tubers. Major problems: second growth, small size, misshapened, poor appearance. No future.

AF1424-7: Round to slightly oval tubers with buff to nearly white appearance. Shallow eyes. Major problems: irregular surface and misshapened. Poor appearance. No future.

Century Russet: Round to oval to oblong tubers. Wide range in tuber size. Wide range in russetting--from netting to fairly heavy russetting. Second growth. Poor appearance. No future.

Superior: Round to oval shaped tubers with light cream appearance. Apical end tends to be deep. No uniform size. Some netting, trace of second growth. May have sizing ability, but poor appearance. No future. Larger tubers have irregular surface.

AF1433-4: Round tubers with buff appearance. Pitted scab could be problem. Larger tubers have irregular surface. Very little second growth. Trace of scab. No future.

B0856-4: Oval shaped tubers, almost russet-type. Medium netting to heavy russetting. Major problem: irregular surface and misshapened. Poor appearance. No future.

B1004-8: Oval to slightly oblong tubers, medium russetting. No second growth. Small size. Larger tubers have irregular surface. No size.

Introduction to Observational Trials

Seventy-seven entries from various parts of the country were evaluated in a replicated field trial located at the Ohio Agricultural Research and Development Center, Wooster, Ohio.

Methods

The seed samples when received were stored under recommended temperatures and humidity conditions. A randomized complete block design with at least two replications of each entry was used. Soil type was a welldrained Wooster silt loam with a pH 6.7 and phosphorus level of 112 lb/A and potassium level of 206 lb/A according to the analytical procedures of the Research and Extension Analytical Laboratory at the Ohio Agricultural Development Research and Center. Fertilization consisted of 600 lb/A of 10-20-20 disked in prior to planting and 600 lbs/A 10-20-20 banded at planting.

Following harvest on September 18, samples for chip quality evaluation only on those that we felt might have potential for Ohio were then taken to the pilot plant at The Ohio State University, Columbus, OH. Samples were held at ambient temperatures until early October (approximately 20 days) when chipping and specific gravity determinations were made. In addition, other samples were graded for market quality. At the time, 10 tubers were taken at random from each replicate and checked for hollow heart and other internal defects.

Results

This year conditions were ideal for making firm decisions on a number of cultivars. Out of the seventy-seven entries, only 20 entries were accepted for further evaluation (Tables 4, 5, 6). The reason for the dismissal of the other fifty-five entries are found in Table 7.

Specific comments on promising cultivars and selections follow below:

B1240-12: Round tubers with medium buff appearance, shallow eyes, shallow apical end. Holds shape quite well, may have surface scab problem. Keep--promising.

B1145-2: Round tubers with medium red appearance. Smooth tuber surface. Shallow eyes and shallow apical end. Fairly uniform tubers. Good skin texture. Promising.

B1492-10: Round tubers with medium to dark red appearance. Medium to small size. Promising. Fairly uniform. Try again.

B1091-29: Round tubers with netted appearance. Some tubers have an irregular surface. Deep apical end. Some tubers have an irregular surface. Try again.

B1344-18: Round to slightly oval tubers with smooth surface. Attractive appearance. Try again.

B1415-7: Round tubers, fairly smooth texture, shallow eyes. Attractive appearance promising. Keep. Try again.

B1416-2: Medium size tubers with fairly smooth surface, but wide range in size. Promising. Keep.

B1321-21: Round tubers with fairly smooth surface. Uniform netting. Field sprouting is present. Trace of second growth. Keep for processing.

B1206-10: Round to slightly oval, light to medium netting. Appears to hold shape quite well. Promising--keep. Try again.

B1083-51: Round to slightly oval tuber with shallow eyes and shallow apical end. Attractive tubers. Promising. Try again.

R19-20: Fairly rough tuber shape, but wide range in size. Relatively smooth surface. Promising. Try again.

R41-11: Round, with slightly netted surface. Eyes tend to be indented. May be ok for processing. Try again.

R170-66: Round tubers with some netting. Wide range in irregular surface. Surface tends to have "flaky" appearance. Try for processing. Save.

R19-7: Round tubers with smooth surface. Shallow eyes. Uniform size and shape. Promising.

CF7523-1: Round to slightly oval tubers with a creamy white appearance. Eyes tend to be slightly deep. Appears to yield well. May have tendency for second growth.

Q3-12: Round to slightly oval tubers. Many with irregular surface. Severe scab problem. Second growth is present.

B0985-1: Round to oval, fairly smooth, dark red, shallow eyes. Wide range in size. Tuber tends to have irregular surface. Medium red appearance.

B0811-4: Medium red. Fairly uniform but small. Some tubers have an irregular shape.

BO564-9: Round to slightly oval tubers with heavy netting. Bud and apical ends are shallow. Promising. Processing.

B1004-8: Wide range in shape--oval to oblong. Light to medium surface. Second growth could be problem. Larger tubers tend to have rough appearance. Keep and try again.

ROMINA	84	v.late	214	Round tubers, cream colored surface. Major problems: second growth, much greening, and irregular surface.
PICASSO	67	v.late	185	Round to slightly oval tubers with cream colored surface containing some red blotches. Field sprouting is present. Second growth.
ISLAND SUNSHINE	66	v.late	144	Round tubers with cream colored surface. Small size. Much second growth. Irregular surface.

Oregon

A.Mosley, D. Hane, S. James, K. Rykbost, C. Shock, B. Charlton and E. Eldredge

Introduction

Russets, chippers, reds, and specialty varieties were compared on sandy loam in field trials at Corvallis. Area soils are typically wet through early May. Most crops are harvested in mid-September to avoid fall rains. Growing seasons are relatively short and yields are low compared to most eastern Oregon sites.

Late blight is a perennial problem in the Willamette Valley because of heavy dew and cool, overcast, humid weather. Some of the entries in the Corvallis variety trials showed decay despite a fairly rigid spray program. Late blight will decimate area potato crops in the absence of a good preventative program. Results of 1997 late blight resistance screening trials effectively illustrate this point.

The Oregon Statewide Trial is conducted on branch stations at Hermiston, Klamath Falls, Madras and Ontario and reflects most conditions encountered by Pacific Northwest growers farming east of the Cascades. Entries are typically compared in the Statewide for two years before advancement to the Tri-state Trial for two years and finally to the Western Regional Trial for two or more years.

Methods

Corvallis Performance Trials

The Statewide trial was grown using commercially acceptable methods common to the four production areas.

Corvallis production specifics included the following:

- SEED
 Hand cut on 5/12 5/16
 Treated with Tops 2.5D (1 lb./100 lbs. seed)
- FIELD PREPARATION
 Moldboard plowed on 5/18
 Rotera (horizontally oscillating spikes
 approximately 6 inches long) on 5/20
 15-15-15 broadcast preplant (500 lbs./a) on
 5/20
 Rotera on 5/20 (incorporate)
- PLANTING DATES
 Performance trials: 5/24
 Late blight screening trial: 5/21 & 5/24 (red-skinned entries)
- TRIAL DESCRIPTIONS
 Performance Trials: Randomized Complete
 Block Design (RBCD) w/ 4 reps, 34"
 between-row spacing, 25' single-row plots, 9" in-row seed spacing.
 Late Blight Screening Trial: RCBD w/ 4 reps, 34" between-row spacing, 15' single-row plots, 9" in-row seed spacing, all plot rows bordered by R. Burbank rows
- CULTIVATION & HILLING 6/25 with two-row disc hillers
- FERTILIZATION 500 lbs./a 15-15-15-9 broadcast preplant 500 lbs./a 15-15-15-9 banded @ planting
 - PESTICIDES
 Tops 2.5D 1 lb./100 lbs. seed
 Di-syston banded @ planting 2.75 lbs. a.i./a
 Metribuzin 0.5 lb. a.i./a post-plant, preemergence on 6/2
 Bravo 720 @ 1.5 pints/a on 7/18, 8/1, 8/13,
 8/29, 9/9
 Ridomil MZ58 @ 2lbs./a on 7/25
 Diquat 1 pint/a + X-77 Spreader 8 oz./a on
 9/9
- IRRIGATION 5/24 - 9/9: 6.0 inches 11.1 (irrigation + precipitation) from planting to vine-kill [9.5" in '96 & 12.2" in '95]

13.9 inches (irrigation + precipitation) from planting to harvest [11.2" in '96 & 17.0" in '95]

- VINE REMOVAL two-row chain flailer on 9/10
- HARVEST Performance Trials: 9/24-9/25 Late Blight Screening Trial: 9/25
- WEATHER
 Growing Season
 Avg. Minimum Temperature = 51.4
 (49.9 in '96)
 Avg. Maximum Temperature = 78.7
 (80.8 in '96)
 Avg. Mean Temperature = 65.0 (65.3 in '96)

Number of Days with Temperature ≥ 90° F May = 0 (0 in '96, 2 in '95) June = 0 (1 in '96, 7 in '95) July = 1 (12 in '96, 9 in '95) Aug. = 9 (9 in '96, 9 in '95) Sept. = 1 (1 in '96, 7 in '95)

Total Rainfall

From Date of Planting to Vine-kill = 5.1 inches [1.8" in '96 & 2.5" in '95]

From Date of Planting to Harvest = 7.9 inches [3.5" in '96 & 7.3" in '95]

MISCELLANEOUS

Growing season temperatures were slightly cooler than during the previous 2 yrs. and temperature fluctuations were not as severe as in years past.

Late blight appeared about July 15 (slightly earlier than normal). Some parts of the field were severely affected. The disease was difficult to contain with our spray program. Some tuber decay occurred in storage, especially in Russet Norkotah, for example.

Harvesting conditions (soil moisture, temperature, etc.) were wetter than desirable.

Late blight resistance screening

Cultural methods for the late blight screening trial were basically identical to

those used for variety performance trials. However, the blight trial was planted almost a month later (June 21 and 24) to maximize canopy density late in August when late blight pressure was highest. Matrix was applied at recommended rates post-crop-emergence in an unsuccessful attempt to control weeds season-long. Russet Burbank was planted in every other row in order to provide a common border for all plots. Late blight infection was encouraged by withholding all fungicide sprays. Most plants were totally dead by mid-September.

Statewide performance trials

Statewide trials were grown using management practices common to each of the four producing areas.

RESULTS AND DISCUSSION:

Chipping trials

Nine chipping varieties and selections were compared at Corvallis. U.S. No. 1 yields ranged from 353 (AC88357-3) to 586 (ATX85404-8) cwt/acre (Table 1). Four entries outyielded Atlantic, the standard (421 cwt/a). AO91812-1, AO91812-2 and ATX85404-8 produced more than 500 cwt/ac of U.S. No. 1 potatoes. Poor grade-out significantly reduced No.1 yields of Chipeta and NorValley. Oversize was a major concern with Chipeta which produced No. 1 tubers averaging 9.9 oz.

Chipeta was relatively susceptible to knobbiness, growth cracking, and greening (Table 2). Hollow heart was not a factor for most entries but AO91812-2 showed about 5%. ATX85404-8, A88431-14 and Atlantic

showed lower levels of 3.4, 3.3 and 1.7%, respectively. AC88357-3 produced unacceptable levels of internal necrosis with 43.4% of the tubers affected.

Specific gravities ranged from 1.081 for Chipeta to 1.089 for Atlantic, the standard, to 1.101 for A88431-1 (Table 3). A88431-1 showed exceptionally good fry color at harvest with an Agtron reading of 46.0 compared to 43.7 for Atlantic and 38.8 for Chipeta. Chipeta seemed to produce darker fries than any other entry at harvest. However, a close examination of statistical significance in table 3 shows few differences in chip color.

Our 40°F cooler failed due to mechanical problems, so December data are limited to fry color from 50°F and sprout percentages and lengths. Interestingly, A88432-1 which fried extremely light at harvest was no better than most other entries on December 15. Only Chipeta tended to produce chips significantly darker than most others. Chipeta showed fewer, shorter sprouts on December 15 suggesting that it might be slightly later maturing and have a longer dormancy. ATX85404-8 appeared to have a very short dormancy as did NorValley.

Based on all factors, the two Oregon selections AO91812-1 and AO91812-2 appeared to have considerable promise, especially for long-season production areas. ATX85404-8 also performed well with the exception of long-term storage. We noted in previous tests that it sprouts early and severely.

Reds

Several red selections yielded well compared to the checks [Dark Red

Norland (444 cwt., U.S. No. 1), Red LaSoda (404 cwt), and Sangre (512 cwt/a) (Table 4)]. Notable selections included CO86218-2 (500 cwt/a), NDO4588-5R (531 cwt.), and NDO4300-1R (536 cwt/a). Both of the latter entries produced very few 2's and culls

External defects were minimal except for 15.8% growth cracks in CO86142-3 (Table 5). CO86218-2 showed some tendency toward hollow heart with a level of 6.7% but the two high-yielding Oregon selections, NDO4588-5R and, especially, NDO4300-1R were generally resistant to both external and internal defects. Based on these data, NDO4588-5R and NDO4300-1R appear to be especially interesting among this group of entries. CO86218-2 also shows a great deal of promise because of its excellent appearance.

Specialty varieties

Characteristics and field performance of 12 mixed gourmet types are summarized in Tables 6 and 7. Because of a broad range of shapes and sizes, grading these cultivars fairly was especially difficult. Total yields may, therefore, be more interesting to the reader than U.S. No. 1 vields. Yukon Gold remained a very good choice among round, yellowfleshed entries. German Butterball with buff skin and yellow flesh was also quite attractive. The Oregon selection AO90319-1 was promising with russeted, slightly round, yellow-fleshed tubers. NDC4069-4 was also interesting because of its red skin and flesh; however, this selection was basically eliminated by metribuzin injury. Red Gold tubers were also quite attractive.

Russets

Several Oregon selections performed well relative to Russet Burbank and Russet Norkotah (Tables 8 and 9). AO87277-6, AO88103-3 and AO91522-4 produced relatively good yields and much higher solids than Norkotah. Russet Norkotah and NDD840-1 showed a relatively high incidence of tuber decay, probably related to late-season late blight infection. AO87277-6 and AO91522-4 are probably the two most interesting selections among this group for Willamette Valley conditions. The former may hold more promise for processing because of slightly higher solids. AO88103-3 showed an unacceptably high level of hollow heart with 23.3% of the tubers affected. The two other high-yielding Oregon selections were relatively free of both external and internal defects

Late blight screening

Twenty-seven white and russet varieties were compared for foliar and tuber resistance to late blight infection in unsprayed fields at Corvallis (Table 10). By early September, most varieties showed almost total foliar death and differences in leaf loss among the entries were minimal.

However, significant differences in late blight tuber infection were evident at harvest. Tuber infection levels ranged from 0 to more than 52%. Infection levels were even higher in similar trials in 1996. Russet Burbank showed moderate resistance to infection with only 10% of the tubers showing obvious, though relatively mild decay. Among the named varieties included, Atlantic was most resistant with only 7.5% infection

(1.3 severity rating) compared to 10% for Russet Burbank, 27.5% for Russet Norkotah, 32.5% for Chipeta and 42.5% tuber infection for Ranger Russet. Ranger Russet, Russet Norkotah, and Shepody were markedly susceptible in 1996 trials as well

Breeding selections showing some resistance to late blight tuber decay include: A82360-7, 10% infection/1.0 severity rating; A8792-1, 2.5% infection/1.0 severity rating; A88338-1, 0 infection/0.5 severity rating; A082611-7, 2.5% infection/0.5 severity rating; and COO83008-1, 5.0% infection/0.8 severity rating. These results will be used by western breeders to produce blight-resistant populations for varietal development purposes.

Resistance of several reds to tuber infection was also evaluated at Corvallis. No differences in infection were evident (Table 11). CO86142-3 showed some tendency toward resistance.

Oregon Statewide Trial

Twelve of 19 entries in the Statewide Trial (Tables 12 and 13) were either retained for further state tests or advanced to the Tri-state and Western Regional Trials. AO900114-1, AO88103-3, AO92007-2, AO92016-3 and AO92017-6 appeared to have excellent multi-purpose potential, especially AO88108-3. The two chippers, AO91812-1 and AO91812-2, produced excellent yields and good chip color but were late maturing. These entries may have good potential for long season areas. AO90319-1 produced attractive russet-skinned, yellow-fleshed tubers which may be of interest to specialty growers.

Oregon Table 1. Yield, grade, and size distribution of 9 chipping varieties and selections at Corvallis, OR. 1997.

Pennsylvania

B.J. Christ, M.W. Peck, and D.M. Petrunak

The potato evaluation trial was conducted at the Russell E. Larson Agricultural Research Center at Rock Springs, PA. This trial is part of an extensive and on-going project that evaluates promising clones for yield and chip processing potential. Clones that are identified as excellent performers are then evaluated in regional trials across Pennsylvania.

Materials and Methods

The trial was planted on May 22 in single row plots as a randomized complete block design with three replications. Plots were 10 feet in length with 36 inches between rows and 8 inches between seed pieces. Fertilization was 300 lb/a of 0-0-62 (N-P-K) broadcast preplanting, 944 lb/A of 10-10-10 (N-P-K) in furrow at planting, and 1 application of 100 lb/A urea ammonium nitrate solution (30% N). The plots were vine killed on September 9 and 15 and harvested on October 8-10.

Specific gravity was determined by the weight-in-air/weight-in-water method. Tubers were held at ambient temperature until they were placed in storage. Samples were chipped five times throughout the winter. Four tubers from each clone were peeled, cut in half and sliced. Eight slices from the center of each half were used for the chip sample and were fried at 365 F. the chip samples were rated on a 1-10 scale according to a modified snack food color chart.

Results

The first seven weeks of the growing season were dry and minimum irrigation was supplied during those weeks. There was adequate moisture during the remainder of the season.

There were numerous lines with yield greater than Atlantic or Snowden. However, there were only a few clones with yield that had chip scores similar to Snowden: B0178-34, B1240-1, B1415-7, B1425-9, AF1426-6, AF1433-4, P32-3, P63-1, P73-2, Q8-2, R17-11, R17-20, NY102, NY115, Reba, MSA091-1, NorValley, ND2470-27, ND3647-6, and ND3828-15.

Of the reds evaluated for skin color, I426-Red, Norland, NorDonna, and ND2225-1R had the best color our of storage. However, the highest yielding lines were Chieftain, B0811-13, B0984-1, and NorDonna. Chieftain and Norland continued to be the best reds in boiling tests.

For tablestock use, there were several lines that out yielded Katahdin or Superior: Reba, E11-45, Salem, Itasca, NY101, NY109, NY110, AF1437-1, AF1480-5, AF1615-1, AF1758-7, and B1452-18. However, only the following lines had acceptable boiling scores: Reba, E11-45, Salem, Itasca, NY101, NY109, AF1437-1, AF1758-7, and B1452-18.

Acknowledgments

The evaluation trial was funded by the Pennsylvania Potato Research Program. We acknowledge the provision of seed by Kathleen G. Haynes, USDA-Beltsville; Robert L. Plaisted, Cornell University; Alvin F. Reeves, University of Maine; Richard G. Novy, North Dakota State University; and David S. Douches, Michigan State University.

¹Nov. = Stored at 55 F from November 10, 1997 and chipped on November 18, 1997.

Chip color is based on a 1-10 scale with 1 = lightest, 10 = darkest, 1-5 = acceptable chip color.

² Dec. = Stored at 55 F from November 10, 1997 and chipped on December 19, 1997.

³ Jan. = Stored at 45 F from November 13, 1997 then transferred to 55 F three weeks prior to chipping on January 28, 1998.

⁴ Feb.= Stored at 45 F from November 13, 1997 then transferred to 55 F six weeks prior to chipping on February 17, 1998.

⁵ Jan.= Stored at 45 F from November 13, 1997 and chipped on January 21, 1998.

⁶ Marketable yield = size 2-4.

Texas

J. Creighton Miller, Jr., Douglas C. Scheuring and Jeff W. Koym

Variety Development and Testing

Seedling program. In 1997, 66,226 first year seedlings, resulting from 328 different parental combinations (crosses), were grown for selection on the Barrett Farm near Springlake. Three hundred twenty nine selections were made from this material. The seedlings grown for selection in 1997 represent a substantial increase from the number grown in 1996. The 1997 first year seedlings from Texas were produced during the fall of 1996 at College Station from true seed provided by Joe Pavek in Idaho. The remainder was obtained from Joe Pavek in Idaho (11,267), David Holm in Colorado (9,015), Kathy Haynes in Beltsville, Maryland (3,570), Al Mosley in Oregon (14,631), Rich Novy in North Dakota (16,397), and Bob Hanneman USDA-ARS, Madison, Wisconsin (612).

Adaptation trials. The 1997 growing season was abnormal in several meteorological aspects. Temperatures during the first two months of the growing season were lower than normal. Rainfall and humidity were higher than the seasonal norms. Yields were much lower than normal. The variety and advanced selection trials at Springlake were planted on March 25 and harvested on July 9 (reds) and July 29 (russets).

Fifteen russet advanced selections and the check varieties Norgold-M and Russet Norkotah were tested for their adaptability to Texas High Plains conditions (Table 1). The outstanding entries considering all factors were TX1229-2Ru, TXAV657-27Ru, A84180-8, ATX84706-2Ru,

AO85165-1, COO83008-1, TX1385-12Ru, and ATX84378-6Ru. The yields of TX1385-12Ru and ATX84378-6Ru were significantly lower than in previous years.

The red trial consisted of 17 varieties or advanced selections (Table 2). The outstanding selections were NDC4438-1 and A82705-1R (soon to be named Ida Rose). NDC4438-1 is a red fleshed selection, which produces a large number of creamer (under 4 oz.) tubers. In addition to the check varieties, Viking and Red LaSoda 10, other selections deserving mention include NDTX731-1R and NDTX4271-5R. The selections NDO4323-2 and NDO3994-2 also produced a large number of creamer size tubers. The market continues to pay a premium for small red potatoes with bright red color.

The russet strip trial consisted of 14 advanced selections for which sufficient seed was available for strip plantings of 100 foot rows (Table 3). Three Russet Norkotah strain selections and the check varieties Russet Norkotah and Norgold-M were also included. Strip trials represent a more advanced phase of testing than replicated variety trials. Four random plots of each entry were harvested. The outstanding entries based on overall performance were TXNS112, ATX1385-12Ru, TXNS223, and ATX9202-3Ru. Others deserving mention include Norgold M, ATX92002-2Ru, TX13485-12Ru, and ATX84738-6Ru. As in the past, the Texas stains continue to outperform regular Russet Norkotah.

Three red advanced selections and the check varieties Red LaSoda and Viking were also grown in a strip trial for evaluation (Table 4). The outstanding entry in this trial was DT6063-1R.

Four white and/or yellow flesh advanced selections and the check variety NorValley were also grown in a strip trial for evaluation under Texas High Plains environmental conditions (Table 5). The selections NDTX4930-5W and NorValley were the outstanding entries.

Thirteen selections, selected between 1986 and 1994, and three check varieties were also evaluated for yield and quality (Table 6). The outstanding entries based on general rating were COTX90046-5Ru, ATX90480-4W, and NDTX4930-5W.

Presented in Table 7 are trial results for 18 old European yellow flesh varieties and checks, which were grown from seed maintained in our Texas nursery. None of the entries performed better than the check varieties Yukon Gold and Saginaw Gold. Most of these varieties are late in maturity.

Texas also participated in the Russet, Chipping, Red, and Specialty Western Regional Cooperative Trials. Results from these trials are reported elsewhere in this report. Ten other trials, including a Winter Red Trial in the Lower Rio Grande Valley on the Mexican border, were also conducted and are reported in the 1997 Texas Potato Breeding Report.

Virginia

S. B. Sterrett and C. P. Savage, Jr.

Introduction

Trials were conducted at the Eastern Shore Agricultural Research and Extension Center in Painter, Virginia. Promising clones were evaluated for yield, tuber quality and appearance, vine and tuber maturity, processing (chip) potential and freedom from internal and external tuber defects. To address potential marketing niches, red-skinned and russetted clones were also evaluated for suitability in this growing area.

Methods

All trials were planted on a Bojac sandy loam soil. Germplasm evaluation trials were planted on April 3 in single-row plots 25 feet in length with 3 feet between rows, and 12 inches between seedpieces within the row for all except the red trial that was planted at 8 inches within-row spacing. Transgenic evaluation trials were planted on April 8 in single row plots 35 feet in length, 12 inches between seedpieces for Superior and 15 inches for Snowden and bordered by a non-transgenic guard row between each plot. Trials were planted using a randomized complete block design with 4 replications except Snowden transgenic trial, which had 8 replications. Fertilizer (100 lbs. N, 43.7 lbs. P, and 83 lbs. K/A) was banded at planting with carbofuran (3 lb. ai/A) + immidacloprid (0.3 lbs. ai/A) banded in the furrow for Colorado potato beetle control. Nitrogen (50 lbs./A) was sidedressed on May 20. Linuron (0.5 lbs. ai/A) and metolachlor (1.5 lb. ai/A - germplasm; 2.0 lb. ai/A - transgenic trials) were applied at dragoff on April 26. Germplasm trials received 2.75" of irrigation and the transgenic trials received 4.0" in June and early July. Round-white and red-skinned trials were harvested July 8, russet trial on July 10, and transgenic on July 21. Specific gravity was determined by weight in air/weight in water method. Chip samples were held at ambient temperature and chipped 2 days after harvest.

Seasonal Observations

Cold, wet weather delayed planting by three weeks. Cool temperatures persisted through May. Reduced rain fall in May and June is reflected in the increased percentage of external tuber defects in some clones.

Results

Round-white Trial. Marketable yield of B1321-22 and B1425-9 was significantly greater than Superior. Marketable yield of B1206-10 was significantly lower due, in part, to severe growth cracks. Specific gravity of B1425-9 was similar to Atlantic but late vine maturity, heavy stolens, and unattractive tuber appearance precludes additional testing in this growing area.

Chip Trial. Marketable yield of several clones was significantly lower than Atlantic. Improved chip color over Atlantic was recorded for B0178-34, B0766-3, B1375-14, B1428A-3 and NYP73-2. Of these, only B0178-34 and NYP73-2 had specific gravity similar to Atlantic. Incidence and severity of internal heat necrosis (IHN) was less than Atlantic except for NY112. Attractive tubers and apparent high yield potential, and freedom of tuber defects of B1240-14 and B1429A-3 warrant additional evaluations for fresh market potential.

Commercial. Marketable yield of Carlita was significantly greater than Concurrent; Obelex, and Rikea was significantly lower than Superior. Tubers of Rikea were very susceptible to IHN, more so than any other clone evaluated in 1997. Tubers of Adora and Carlita were attractive and relatively free of internal and external defects. Both of these, particularly Adora with early tuber maturity and consistent yellow flesh color, may have potential as commercial varieties in this area.

Red-Skinned Trial. Total and marketable yield of Red LaSoda and Romano were significantly greater than B0811-4, but significantly less than Dark Red Norland. However, unattractive tubers and late skin maturity of Romano will limit grower acceptance.

Russetted-Skinned Trial. Although marketable yield of B9922-11, Century, and B1004-8 was significantly greater than BelRus, the greatest percentage of tubers over 8 oz. was noted for B9922-11. Susceptibility to growth cracks was a concern for B9922-11 and, to some extent, B1004-8.

Transgenic Trial. Emergence of SPMT15-29, SPMT15-224, SPMT15-250, SPMT15-259, and SPMT15-270 were significantly slower than the nontransgenic standard at 27 days after planting (DAP). However, the final standcount was similar for all Superior entries. In the Snowden trial, plant emergence of SDMT15-24 was significantly less than SDMT15-40 at both 34 and 41 DAP. Stem count, as well as, plant vigor and crop uniformity ratings of SDMT15-24 were significantly lower than the non-transgenic standard.

Marketable yield of all transgenic Superior clones was similar to the non-transgenic standard except SPMT15-245, which was lower. However, the size distribution of only SPMT15-270 was similar to that of the Superior standard, with a greater percentage of tubers less than 2.5" diameter reported for the other transgenic Superior clones. Average total tuber weight was also lower than the standard for all transgenic Superior clones except SPMT15-29 and SPMT15-270. Similar trends were noted for six of the transgenic clones for average marketable tuber weight.

Marketable yield of SDMT15-40 was similar to the standard Snowden. Average total and marketable tuber weights were similar to all Snowden entries.

Tuber characteristics of transgenic Superior clones were similar to the standard. Heat sprouts and second growth of most Superior entries was appreciable, reflecting the rather sudden shift in the growing season from cool and wet to hot and very dry. Tuber defects appear to less of a problem for the Snowden clones.

The appearance of all transgenic Snowden clones were significantly below that of the non-transgenic standard. All transgenic Snowden were later in tuber maturity than the standard.

Ratings

Vine and tuber ratings were completed using the rating system of the U.S. Department of Agriculture regional project NE184. For vine ratings, maturity: 1 = senesced, 9 = totally green; air pollution: 1 = defoliated, 9 = no visible symptoms. For tuber ratings, shape: 1 = round, 5 = oblong, 9 = very long (cylindrical); appearance: 1= very poor, 9 = excellent; skin maturity: 1 = totally peeled during harvest and grading, 9 = skin intact; and tuber defects: 1 = severe, 9 = none. Ratings of heat necrosis were made on 20 tubers in the size range $2\frac{1}{2}$ to $3\frac{1}{4}$.

Acknowledgments.

We thank Wise Foods, Inc., Berwick, Pennsylvania for their assistance in these evaluations and chip color determinations. We gratefully acknowledge provision of seed by Kathleen G. Haynes, USDA-Beltsville; Robert L. Plaisted, Cornell University; and Alvin F. Reeves, University of Maine. The support of this project by Can AGRICO Potato Corp., Grand Falls, New Brunswick; Global Agri Services, Inc., Fredericton, New Brunswick; and Hettema, Fredericton, New Brunswich is greatly appreciated.

Wisconsin Potato Variety Trials

Horia Groza, Bryan Bowen, and Jiming Jiang.

Evaluations of the performance of the advanced selections are done within the breeding program in the fith and sixth field generations in replicated trials at two locations and seventh and eighth field generation are in the North Central Regional Trial (NCRT).

The field trials were conducted in Rhinelander, under shorter and colder season conditions, and Hancock, under longer and warmer season conditions, on irrigated sandy soil. They were planted in a randomized block design with single row plots of 20 hills/plot and 12"x36" spacing. Planting, vine killing and harvest dates: (1) in Rhinelander -5/8/97, 8/20/97 and 9/3/97; (2) in Hancock - 4/22/97, 8/25/97 and 9/15/97. The NCRT was conducted in Hancock under exactly the same conditions and dates as the previously mentioned Hancock trials.

The yield was graded into A size (>1%" diameter), B size (<1%") and culls. The vigor at the second blooming, early blight at the beginning of August and vine maturity were scored on a 1-9 scale (1 = very weak, very susceptible or very early, respectively). Common scab and Rhizoctonia attack on tubers was scored on a 1-9 scale (1 = very susceptible). The tubers were described for shape (1=round,

5=oval, 9=long) and shape uniformity (9=very uniform). Five tubers larger than 8 oz were cut lengthwise for rating internal tuber defects (hollow heart, internal brown spot and vascular discoloration). A general preference score for tuber external and internal appearance has been used (1=undesirable, 2=acceptable, 3=good, 4=very good). The specific gravity was determined by measuring the weight in air and water and the table values are expressed as $(SG - 1) \times 1000$. The chip color was scored from 1 to 10, according to the PCII Color Chart (where 1 is the lightest and 4 is the maximum accepted), for the frying time interval until "the bubbling" stops (which measures the reducing sugars factor and eliminates the solids factor). Measurements of chip color were also done with Colorquest 45/0 (a HunterLab spectrophotometer), for lightness (L) in the range black-white, where the aceptable color values are equal or over 60. The chip color for the trials including the advanced selections was determined at reversion (a month storage at 55F) and after three month storage at 40F with and without reconditioning (two weeks at 65F). For the NCRT the chip color was measured when processed freshly harvested and after 3 month storage at 40F (without reconditioning).

Experimental Line Characteristics

MN 16180 - medium late to late, vigorous haulm, medium susceptible to early blight, resistant to scab, attractive round tubers, light skin, high set, medium size, no internal defects, good solids, good chip color, good cold chipper, ranked 2nd in the NCRT in 1997.

MN 16489 - medium late to late, vigorous haulm, medium susceptible to early blight, round oval tubers of variable size, greening, slightly pink eyes, resistant to scab, medium solids, good chip color, good cold chipper.

MN 16966 - very late, vigorous vines, medium resistant to early blight, very high yield, long tubers, offshape, lenticels, good solids, acceptable chip color when processed freshly harvested, internal brown spot incidence, medium susceptible to scab.

MSB 073-2 - medium late, medium susceptible to early blight, medium susceptible to Rhizoctonia, uniform round tubers with good netting, good chip color when processed freshly harvested, good solids.

MSB 076-2 - late, very vigorous haulm, medium resistant to early blight, medium resistant to scab (pitted type), medium susceptible to Rhizoctonia, hard vine killing, fairly uniform round tubers with good netting, very good skin set, high yield, excellent solids,

good chip color.

MSB 106-7 - medium early, medium vigorous haulm, medium susceptible to early blight, fairly resistant to scab, long blocky tubers of variable size, low solids, not acceptable fry color, susceptible to blackspot.

ND 2225-1 R - medium early to early, medium vigorous haulm, susceptible to early blight, no incidence of pitted scab in 1997, excellent red color, very attractive tubers, low incidence of vascular discoloration, medium susceptible to Rhizoctonia, ranked the first in the NCRT in 1997.

ND 2676-10 - early, less vigorous haulm, susceptible to early blight, medium resistant to scab, round smooth tubers, very high incidence of vascular discoloration, medium solids, very good chip color, a good cold chipper.

ND 3828-15 - medium early, susceptible to early blight, large round-oval tubers, growth cracks, high incidence of hollow heart, medium resistant to scab, medium low solids, good chip color, a fairly good cold chipper (except when reconditioned from 3 month storage at 40F).

W 1100 R - medium early (10 days later than Dark Red Norland), medium vine vigor, susceptible to early blight but more resistant than D.R. Norland, good yield, attractive red tubers, uniform round tuber shape, good and stable color.

W 8475 R - medium late, low vine vigor, medium susceptible to early blight, 50-70% B size tubers, high set (up to 25 tubers/hill), good red color, round tubers, no internal defects, excellent for special market ("steamers" and "creamers")

W 1151 rus - medium early (10 days later than Russet Norkotah), less vigorous haulm, medium susceptible to early blight (significantly more resistant the Russet Norkotah), fairly resistant to scab, very attractive blocky medium heavy netted tubers (Norkotah type), early tuber set, sensitive to hollow heart.

W 1313 - medium late, vigorous haulm, fairly resistant to early blight, uniform round-oval tubers, shallow eyes, netting, good skin set, medium susceptible to pitted scab, susceptible to shatter bruises, excellent solids, good chip color at reversion and after 3 month 40F storage, especially under stress inducing sandy soil conditions.

W 1348 rus - medium late, vigorous vines, Russet Burbank type, dual purpose potato, higher yield and better fry color than R. Burbank, uniform long tubers with medium dark net (some tubers with variable intensity of darkness), medium resistant to common scab and Rhizoctonia.

Standard variety characteristics.

Atlantic - medium late to late, fairly resistant to early blight, very good yield, high proportion of hollow heart, high solids, good chip color from freshly harvest but not good at reversion and after 40F storage.

Snowden - medium early, medium resistant to early blight, smaller tuber size, shallow to medium eyes, occasional growth cracks, medium low incidence of vascular discoloration, good solids, excellent chip color at reversion, after 3 and 6 month 40F storage (when reconditioned).

Norchip - medium early, medium susceptible to early blight, very resistant to scab, growth cracks and offshape tubers, medium low incidence of hollow heart and vascular discoloration, very tolerant to internal defects, good solids, good chip color.

Red Pontiac - late, fairly resistant to early blight, pale red color, big size, round tubers, growth cracks, hollow heart, very susceptible to scab.

Dark Red Norland - early, susceptible to early blight, good red color which sometimes fades in the hot sandy soils of Hancock, good yield, hollow heart incidence.

Russet Norkotah - medium early, susceptible to early blight and early dying, medium susceptible to scab, extremely attractive tubers with medium dark net.

Russet Burbank - late, vigorous vines, fairly resistant to early blight and scab, light net, knobby tubers, medium good solids, acceptable fry color when processed freshly harvested, hollow heart and vascular discoloration.
